Lieutenant E. V. Whitby has been transferred from the Military Hospital at Kilworth Camp to Fermoy. Lieutenant J. R. Hudleston has left the Aldershot Command and embarked for a tour of service in Jamaica. Lieutenant C. Helm has been transferred from the Military Hospital at the Curragh Camp to Dublin. Lieutenant M. Burnett has taken up duty at the Military Hospital, Gosport, on transfer from Winchester. The following Lieutenants have embarked for a tour of service in India: C. J. H. Little, S. J. Barry, E. P. A. Smith, J. M. Elliott, F. R. B. Skrimshire, E. A. Strachan, H. W. L. Alcott, and O. W. J. Wynne. Lieutenant H. J. G. Wells has been appointed to the Military Hospital at Rawal Pindi Cantonment to undergo a special course in Indian sanitation and hygiene. Lieutenant W. Stewart has joined at Lucknow. Lieutenant F. C. Cowton has been appointed to the Eastern Command. Lieutenant N. T. Whitehead has taken up duty in the London District. Lieutenant H. S. Blackmore has been appointed to Bangalore. Lieutenant W. V. Corbett has been appointed to the London District. Lieutenant R. B. Price has taken up duty at the Queen Alexandra Military Hospital. Lieutenant A. S. Heale has embarked at Malta for a tour of service in India.

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of the following officer from Lieutenant to Captain: Walter Oliphant Walker (dated Oct. 22nd, 1913).

The King has approved of the admission of the undermentioned to the Indian Medical Service as Lieutenants on probation (dated Jan. 31st, 1914): George Henry Mahony, William Ross Stewart, Gordon Covell, John Gregory Owen Moses, Koty Venkata Ramana Rao, Hari Chand, Jacob William van Reenen, Venkatasubba Mahadevan, Alured Charles Lowther O'Shee Bilderbeck, Maurice James Roche, Basil Fraser Beatson, Nehchal Das Puri, Prabodh Chandra Roy, Monindranath Das, Jagannath Balkrishna Vaidya, Joseph Martin Reeves Hennessy, William Mawhood Lupton, Alfred Glen Cowper, Hubert Horan Brown, and Charles Henry Niel Baker.

The King has approved of the confirmation of the commissions of the following Lieutenants on probation with effect from July 26th, 1913: Sahib Singh Sokhey, Atul Krishna Sinha, Subramanya Doraisamy, Allan Seddon, James Findlay, William Collis Spackman, Jyotish Chandra De, Nanalal Maganlal Mehta, Robert Morrison Easton, Charles Henry Powell Allen, Peregrine Stephen Brackenbury Langton, and Reginald Victor Martin.

The King has approved of the retirement of the undermentioned officers:—Surgeon-General Henry Wickham Stevenson, C.S.I. (dated Jan. 10th, 1914). Major Maxwell Dick (dated Feb. 13th, 1914).

Surgeon-General H. W. Stevenson, C.S.I., has relinquished charge at Bombay.

Colonel P. Hehir, Assistant Director of Medical Services to the Sixth (Poona) Division, has been selected to officiate as Deputy Director at Army Headquarters during the absence on seven months' leave of Colonel H. Hendley. Colonel R. W. S. Lyons has taken up duty as Assistant Director of Medical Services to the Third (Lahore) Division of the Northern Army in India.

Lieutenant-Colonel J. Penny has been granted an extension of leave of absence home from India on medical certificate for four months. Lieutenant-Colonel J. M. Crawford has been appointed Civil Surgeon at Benares on return to India from leave of absence.

Major W. T. McCowen has arrived home on leave of absence from India. Brevet Major S. R. Christophers, Assistant Director to the Central Research Institute at Kasauli Cantonment, has been appointed to officiate as Director during the absence on leave of Major W. F. Harvey, or until further orders. Major R. F. Baird, civil surgeon at Benares, has been transferred to Gonda. Major J. G. Swan has joined at Dalhousie. Major R. M. Dalziel, superintendent of the [illegible] home on leave of absence [illegible] C.I.E., has been reverted [illegible] Director of the Bombay [illegible]

Captain H. H. Broome has taken up duty as Professor of Anatomy at the Government Medical College, Lahore, vice Captain R. H. Bott. The services of Captain H. R. Dutton have been replaced at the disposal of the Government of Bengal Presidency. Captain J. Morison has arrived home on leave of absence from India. Captain E. W. Witham, medical officer in charge of the Assam Valley Light Horse, has been granted leave of absence home from India for one year. Captain A. D. Stewart has been appointed to officiate as Medical Officer of Health at Simla, vice Captain R. A. Need [illegible] deputation duty under [illegible] Government of India. [illegible] in charge of the 38th [illegible] appointed for temporary duty in the Civil Medical Department of Bombay Presidency. Captain H. Halliday, civil surgeon on special duty with the Clerical Services Committee at Lahore, has been appointed to Lyallpur. Captain H. C. Keates, plague medical officer at Lahore, has been appointed Plague Medical Officer at Hoshiarpur. Captain C. G. Seymour has arrived home on leave of absence from India. The services of Captain D. D. Kamat have been placed at the disposal of the Government of Bombay for civil employment.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant John H. C. Grene resigns his commission (dated March 4th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd Home Counties Field Ambulance, Royal Army Medical Corps: Horace Townsend Newman Merrick to be Lieutenant (dated March 4th, 1914).

2nd London Clearing Hospital, Royal Army Medical Corps: Captain Frederick William Higgs, from the List of Officers attached to units other than Medical Units, to be Captain [illegible]

[illegible] *than Medical Units.*—Lieutenant [illegible] Captain (dated Oct. 29th, 1913). [illegible] resigns his commission, and is [illegible] his rank and to wear the [illegible] 4th, 1914).

[illegible] *than Medical Units.*—James Ettershank Gordon Thomson to be Lieutenant (dated Dec. 27th, 1913). [illegible] (dated Jan. 3rd, [illegible] Lieutenant, 3rd [illegible] West Surrey Re[illegible] 1914).

Supernume[illegible] Quartermast[illegible] with the Un[illegible] Officers Trai[illegible] the medical [illegible]

DEATHS IN THE SERVICES.

Deputy Inspector-General [illegible] George Moore, R.N., retired, at his [illegible] Bristol, in his eighty-seventh [illegible] in 1848, was promoted to st[illegible] surgeon in 1870, becoming de[illegible] in which year he retired. As senior assistant-surgeon he served in the *President*, flagship of Rear-Admiral Price, during the Russian war in 1854-55, and was present at the [illegible] [illegible]ded for his services, [illegible]urgeon in 1857). He [illegible] during the civil war [illegible]t the capture of the [illegible]l *Alucausa*, and subsequently on their being forcibly removed from Cartagena [illegible]nts.

[illegible] (retired), i[illegible] 25th. He [illegible]e rank of staff-surgeon in 1890, fleet-surgeon in 1899, and retired in the following year.

Captain Percy [illegible] R.A.M.C., on Feb. 10th, at Sierra Leone, aged 32. [illegible] and was promote[illegible] years in Jamaica he went to Africa, where he served on the West Coast.

THE HEALTH OF THE UNITED STATES ARMY.

The report of the Surgeon-General of the United States Army for the year ending June, 1913, points out that the non-effective rate—that is, the statement of the average number c[illegible] by disease or injury [illegible]e measure of the l[illegible] disease or injury. [illegible]y far the lowest o[illegible] has also improved, and the occurrence of venereal diseases has been controlled. This last improvement is the result of the propagan[illegible] prophylaxis, [illegible] of pay by ac[illegible] diseases. W[illegible] improved sanitation and the exercise of care in the selection of recruits have caused the disease to diminish steadily. A diminution in the admission rate for *malarial fevers is also shown, although the admission*-rate for these fevers in the Philippine Islands was higher than it has been in any year since 1906. "Finally," says the Surgeon General in his introduction, "it is being demonstrated day by day in the camps of Texas City and Galveston that troops properly protected by vaccination against small-pox and typhoid fever can live in camps properly located with the present system of camp sanitation for an indefinite length of time without any increased morbidity among the troops." Attention is again drawn to the great deficiency in the number of hospital corps.

ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.—Some striking comparative figures were presented in the annual report submitted to the general court of governors of this hospital on Feb. 26th. The number of out-patients and the casualties treated showed a remarkable decrease, and was accounted for by the working of the National Insurance Act. The number of out-patients during last year—and the hospital is the largest general hospital south of London—was 8783, against 10,568 in the previous year, and the number of attendances in the out-patients' department 32,197, a decrease of 7532. The casualties were 5396, against 6972, and the casualties dressed in the out-patients' department 11,232, a decrease of 7024. The demands upon the in-patients' department showed an increase. The new president of the hospital for the ensuing year is Sir John H. Luscombe, J.P., High Sheriff of Sussex.

THE WOMEN'S HOSPITAL FOR CHILDREN.—By the kindness of Sir John Bland-Sutton an entertainment was held in the Persian Hall, 47, Brook-street, W., in aid of this young and much needed charity on Saturday last, Feb. 28th. The hospital is at present housed in the Harrow-road, London, W., but a promising start has been made with a building fund, larger premises in the neighbourhood being required. The programme of the entertainment included violin solos by Miss Winnie Game; three songs by Mr. G. Pyman; a series of original dances arranged by Miss Edith Willoughby Brown and accompanied at the piano by Miss J. C. Macdonald, who also composed some of the music; solo dances by three children, Miss Fay Yeatman, Miss Mary Saunders, and Miss Mary Richards; country songs by the three little children of Dr. R. O. Moon; and a fairy tale play for nine children founded on Christina Rossetti's "Goblin Market," the dances here also being arranged by Miss Willoughby Brown. During an interval in the programme, Mrs. Kendal eloquently pleaded the cause of sick children in a brief speech. The entire and considerable profits of the entertainment have been handed to the hospital, Sir John Bland-Sutton having defrayed all expenses as well as having lent his house.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

SCOTLAND.

Tuberculosis in Edinburgh.

CONSEQUENT on the changes found necessary for the administration of treatment and general organisation of tuberculous patients under the National Insurance Act, which include the transference of Poor-law consumptives to the town authorities, a scheme is now on foot for the transference to the corporation of Edinburgh of the Royal Victoria Hospital for Consumption and its allied institutions. In view of the comprehensive scheme to be undertaken by the local authorities it has for some time been considered that all the institutions and agencies at present engaged in the prevention and treatment of tuberculosis in the city should be amalgamated and organised as units of one central depôt. It is therefore proposed that the Royal Victoria Hospital, with its Tuberculosis Dispensary in Spittal-street, and its Farm Colony at Lasswade, should be absorbed by the corporation authorities, who already have increased their accommodation at Colinton Mains Hospital in order to deal with tuberculous cases, and have taken over all patients with positive swabs from the Poor-law institutions within the city boundaries. The provisional conditions of the draft lay down that the Victoria Hospital is not to be used for the isolation of advanced cases, and that as many as possible of the medical staff, nurses, and others at present employed shall be taken over if they are willing to enter the service of the corporation. Further, it is proposed that, notwithstanding the transfer of the other concerns, the present trustees of the Royal Victoria Dispensary shall continue to act under the constitution and rules of that institution in promoting the advancement of medical and surgical science, with reference to tuberculosis and allied diseases, for which purpose the trustees are in possession of various invested funds, and they shall be entitled to receive any fresh moneys left for this object. Such funds may be applied to the establishment of a chair or lectureship in the University of Edinburgh. In the event of this the corporation are to give all reasonable facilities for teaching in connexion with their institutions.

The Care of Imbecile Children in Scotland.

At the fifty-third annual general meeting of the Scottish National Institution for the Education of Imbecile Children Dr. R. D. Clarkson reported that the number of children cared for had been larger than ever before, the average number on the register being 377, or 18 more than last year. The chairman (Sir David Paulin) said that for 53 years the institution had been doing a great national service. Referring to the Mental Deficiency Act, which is to come into operation in May, he said that so far from the Act diminishing the usefulness of the institution it would, so far as regards educable, and perhaps also ineducable, children, place greater demand than ever on the available accommodation. In any case, as there was no immediate prospect of any other accommodation being provided for imbecile children in Scotland, and as the requirements of the Act upon local authorities would at once become urgent, there would necessarily be a great demand upon the accommodation of this institution. At the present time these demands were excessive, and the directors must at once take steps to provide for more patients and thus be enabled better to fulfil its purpose.

The Edinburgh Day Nurseries Association.

At the annual meeting of this association the report showed that the attendance at the nurseries during the past year numbered 26,013, an increase of 846 over the previous year. The accounts showed that, although the annual subscriptions were well kept up, there was a deficiency on the year's work of over £30. The Lord Provost, in moving the adoption of the report, said that the idea of the nurseries was to help those who were prepared to help themselves—namely, the hard-working widow, or the wife whose husband was for any reason out of employment and she was therefore the breadwinner. In addition to these worthy cases, there unfortunately existed many cases where the husband was neglectful, lazy, intemperate, and altogether unemployable, and here the brunt of keeping the home together fell upon the wife. Under these conditions it was a great help and relief to know that the little children were being properly cared for in their absence, and it was for this purpose that the day nurseries existed. That the mothers appreciated what was done for them was evidenced by the fact that of the total expenditure of £507 more than one-half was met by the mothers' payments. The Stockbridge Nursery had recently added a training school for children's nurses to its work, the total expenditure on which for last year showed a shortage of £225. The pupils' fees, however, were only for six pupils at the original fee of £25, and two at the increased fee of £30, whereas the full complement was 14 pupils per annum, which, at £30, would bring in a sum of £420, or nearly enough to balance the expenditure and income. The full number of pupils were now in residence, and it appeared likely from the number of applications which had been received that there would not be much difficulty in the future in keeping up to the maximum, and the school and crèche should become self-supporting.

The Royal Edinburgh Asylum for the Insane.

The annual meeting in connexion with this institution was held on Feb. 23rd, when Dr. G. M. Robertson, the physician-superintendent, read his report. He again strongly emphasised the importance of alcoholism as a cause of insanity, and also stated that there was no evidence to show that the wear and tear of modern life tended to increase insanity, but that rather the opposite seemed to be true. Insanity was more prevalent in rural districts with falling populations, but a cause for this might be found in the migration of the more fit either abroad or to more congested areas.

Post-graduate Teaching in Edinburgh.

In addition to the courses in July, August, and September, already advertised, there will be a special course on midwifery and gynæcology during the latter half of August. Particulars can be had from the secretary, New University Buildings, Edinburgh.

The Newmains Medical Dispute.

Attention has been drawn by me to a dispute between the Lanarkshire Miners' Union and the Newmains doctors, and since then an interesting development has taken place. Last year by large majorities the men employed in Coltness Ironworks, Allanton Foundry, the Coltness Collieries, and Chapel and Morningside Collieries agreed to pay their doctors the flat rate of 2½*d.* per week for attendance on the dependents of workmen. Shortly after the Lanarkshire Medical Association was formed, which, in conjunction with the Miners' Union, formed a scheme of medical service. After a few meetings the flat rate of 2*d.* was agreed upon. The county doctors were much disappointed at the result, and many of the men in the rural areas agreed to come into the scheme only on condition that the agreement was temporary, and that the question of rates in rural areas would get special consideration in the immediate future. The miners' officials agreed at the time that there was a case for the rural doctors, but little so far has been done to remedy matters, and the doctors in the scheme are becoming more and more dissatisfied. A number of these refused to recognise the scheme, but their opposition generally collapsed when the Miners' Union brought pressure to bear on them, and now very few medical men in the county are outside the scheme. The Miners' Union took a ballot of the men in Morningside and Chapel Collieries, when a large majority declared in favour of the flat rate of 2*d.* On the Newmains doctors being notified of the result of the ballot they posted a notice at the pits informing the men that they declined to attend them at that rate, and intimated, in the event of the ballot coming into force on Feb. 27th, the resignation of their appointments. The friendliest relations have always existed between the miners and their doctors, and when the men received the resignation of their doctors they resolved to reconsider the matter and take a fresh ballot, with the result that the previous one was reversed, and a majority of 300 declared in favour of paying 2½*d.* as formerly. The Miners Union now refuses to accept the second ballot of the men, and as the men are in full agreement with the doctors and are resolved to abide by the last ballot notwithstanding the union, a most interesting and piquant situation has now been reached.

Outbreak of Small-pox in Aberdeen.

An outbreak of small-pox has occurred in Aberdeen, four of a family being attacked. The infection, it is supposed, was brought from abroad by a sailor son, who was the first to succumb. This is the first time since 1907 that there has been small-pox in Aberdeen, and then there was only one case, that of a foreign sailor, and during the last 14 years there have been in all only 11 cases in the city. Dr. Matthew Hay, medical officer of health, reported that since the passing of the Vaccination (Scotland) Act, 1907, the number of conscientious objectors to vaccination has rapidly increased in Aberdeen. In 1907 there were only 82; in 1908 there were 210; in 1909, 335; and in 1910, 373. The number of unvaccinated children has not, however, as far as Aberdeen is concerned been reduced in proportion, for the reason that the increasing number of parents who make the statutory declaration of objection is drawn only in part from the class that have been in the habit of consenting to vaccination, a considerable part coming from among those who have hitherto contrived in one way or another to avoid the vaccination of their infants.

Sanatorium Benefit in Aberdeen.

At the first meeting of the new Sanatorium Benefit Committee, held on Feb. 20th in Aberdeen, a letter was read from the Local Government Board approving the proposal to provide 53 beds for Aberdeen county in the proposed joint sanatorium to be erected by the county councils of Aberdeen, Kincardine, Elgin, and Nairn. The county of Banff had also been strongly recommended by the Board to join the joint scheme. The Board also regarded favourably the proposal to provide hospital accommodation for 33 patients. A subcommittee was appointed to confer as to joint sanatorium, &c.

Ross Memorial Hospital, Dingwall.

At the annual meeting of subscribers to the Ross Memorial Hospital, Dingwall, the chairman referred to the great loss the institution had sustained in the death of Dr. J. Adam, and moved that their regret should be recorded in the minutes. A letter was read from Dr. William Bruce resigning his post as senior physician. The chairman expressed the regret that was felt at the retirement of Dr. Bruce, who has been connected with the hospital for upwards of 40 years and had always had its interests so much at heart.

March 3rd.

PARIS.

The Control of Pharmaceutical Specialities.

A DISCUSSION has been in progress for some weeks at the Académie de Médecine in regard to a proposition by the Government for a fresh regulation of the sale of poisonous substances. Many resolutions have been passed, of which two will be of great import should they be accepted by the Government. The first relates to the sale of pharmaceutical specialities which has considerably increased of recent years. Although the sale of secret remedies is absolutely prohibited by law, proprietary pharmaceutical products violate all the regulations which demand that their exact composition shall be given on the box or bottle containing them. They are all sold under some fancy trade name, carefully registered, and the greater part of them contain on their labels nothing more than a list of the diseases for which they are alleged to be useful. Custom allows these preparations to be sold over the counter in all the pharmacies without a medical prescription. As these remedies are widely advertised in the newspapers they constitute an incitement to self-drugging without medical advice. Moreover, many of these preparations contain such powerful poisons as morphia, cocaine, aconitine, digitalin, and strophanthin in quantities that a pharmacist would not be allowed to dispense in any other form without a medical man's prescription. The Academy, therefore, has passed a resolution that in future all these pharmaceutical specialities should be compelled to bear on their labels a complete and precise statement of their several ingredients and the doses thereof. Further, none of those containing drugs on the poison schedule should be allowed to be sold or dispensed without a doctor's prescription. This resolution will doubtless meet with great opposition from the manufacturers of such products who now form a wealthy and powerful corporation, having great influence with the Ministère du Commerce. Another resolution by the Academy deals with prescriptions written in a false name and with a forged signature —a proceeding quite common among morphine and cocaine *habitués.* Some detach prescription blanks in the medical man's waiting-room while he is not looking. They have even had these prescription forms reproduced by printers. Occasionally the pharmacist to whom these prescriptions come suspects that they are irregular, and warns the medical man by the telephone. On many occasions the forgers of these false prescriptions have been prosecuted, but, strange to say, the courts have always been reluctant to regard this act as on a par with forgery in the commercial sense, which is punishable with hard labour. They have considered the punishment too severe for what appeared to them a simple piece of trickery (*supercheric*) in a sick and more or less irresponsible person. The resolution of the Academy demands a special regulation defining the offence when committed under such circumstances and ordaining a punishment therefor. In the case of unscrupulous pharmacists who dispense such prescriptions for their profit, knowing very well that they have been forged, the new regulation will inflict punishment on them also.

Collective Food Poisonings.

Some time ago there occurred at Cholet, Maine-et-Loire, a case of collective food poisoning which attacked 38 wedding guests who had eaten a wedding cake covered with icing. Ten of these died, and two further cases were noted among persons who, though they had not taken part in the feast, had tended the victims. This obviously suggests contagion. Many experiments were made by the local medical jurists, but as they proved contradictory Professor Chantemesse was sent from Paris by the Ministry to investigate, and the Academy received his report on Feb. 17th. Professor Chantemesse holds that it was a case of poisoning by a paratyphoid bacillus, which he found in the blood and in the intestines of the victims, both during life and at necropsy, and which he recovered also from fragments of the toxic icing. The bacillus is motile and belongs to the Gärtner group. Its specific toxicity is weak enough under ordinary circumstances, which accounts for the fact that a veritable epidemic did not arise in the houses where the victims were tended. The investigation showed that the icing cream had been prepared a long time in advance. The white of egg, undoubtedly infected, was poured upon the hot cream, and the whole was placed for a few moments in the oven, where an isolating crust formed on the surface of the cake. Under these conditions the culture of the bacillus in the white of egg took place in an anaërobic medium, as in an *étuve*. The cause of the accident was easily found in the blood of the cook who prepared this cream, and who, although herself in good health, doubtless had carried these bacilli in her intestines for many years, for a retrospective inquiry showed that the same person, whose occupation was to prepare banquets in the neighbourhood, had already given rise in several localities to similar accidents, which had not, however, attracted much attention because they were of lesser gravity. Professor Chantemesse thinks that this bacillus is capable of giving rise to such incidents under favourable conditions. He makes suggestions for the preparation of this sort of cream, and recommends rigorous attention to asepsis of the hands of the persons who prepare it. Moreover, Professor Chantemesse cites in his report a notable case in the reign of Louis Philippe, that of the poisoning of M. Lafarge by his wife, who was condemned to the galleys for life after her case had aroused intense excitement throughout the land. He shows that probably this was a case of miscarriage of justice, for the cake which Mme. Lafarge sent her husband, and which caused his death, seems to have been prepared in exactly the same way as that of the deadly cake of Cholet. Madame Lafarge's conviction was secured by the evidence of the famous Orfila, who demonstrated the presence of arsenic in the organs of the poisoned man by Marsh's test when nine other experts had failed.[1] His evidence was considerably criticised.

The Surgery of the Heart.

Dr. Tuffier has recently communicated to the Académie de Médecine the results of some investigations undertaken by him at the Rockefeller Institute in regard to surgery in diseases of the heart. The surgery of the heart, hitherto limited to the suture of wounds and the search for projectiles, has given some surprising, if hazardous, results. Intervention in regard to the valves has been of no avail. M. Tuffier's researches have shown that the regions of the ventricle, the base of the aorta and of the pulmonary artery allowed of incision without too great hazard; on the other hand, incision of the auricles is always formidable. The circulation of the cardiac muscle may be interrupted for two minutes. The circulation of the cavity of the heart may be suspended by temporarily effacing the two venæ cavæ for three minutes. This may be prolonged to seven minutes if care is taken to irrigate the brain by suitable injection into the carotid; the surgeon must act quickly. M. Tuffier counsels the following operative procedure. Incision in the second intercostal space at the left edge of the sternum, wide opening of the pleura, forcible separation of the ribs, longitudinal section of the pericardium, arrest of the general circulation by compressing the venæ cavæ. As to the incision of the aorta or the pulmonary artery so as to enable the operator to get at the valves, it must be preceded by the placing in the region where the incision is to be of a piece of a vein or an artery which has been kept in cold storage for 24 hours and which must first be sewn on three of its sides to the wall of the vessel. The incision is then made at the base of the artery and the valve is dealt with, and in the case of very great occlusion incised. Immediately afterwards the wound in the artery is sewn up with a fine thread, and above it is sutured, to reinforce it, the fourth side of the piece fastened there in advance. The sequelæ of this procedure, which so far has been practised only on animals, have been very simple. M. Tuffier thinks that there are cases where it might properly be tried in man.

The Internship of the Hospitals and Foreign Students.

There have existed in France during the past 15 years two kinds of diplomas in medicine—the State diploma, which can be obtained only by candidates who possess a baccalaureate and certificates from French schools and universities; and the diploma of the university, for which are accepted the diplomas and certificates of foreign universities recognised as of equivalent value to the French diploma. Practically the diploma of the university is thus the only one open to foreign students, and though the studies are the same it differs from the State diploma in that it does not confer the right to practise in France. This distinction has been made to afford easy admission to students in the French faculties without overcrowding the medical profession with foreigners (as has been the case in the past), who, not being liable for military service, have thus a three years' advantage over Frenchmen. A new rule for the interneship, which has been imposed by direction of the Assistance Publique, enacts, among other rigorous requirements, the written studies for the university diploma as well as for the interneship, and excludes the foreign students. This has produced active protest from all the physicians to the hospitals, who accuse the rule of lack of liberality, and assert that it will keep away from France students who on their return to their own countries would bring honour to French science. Moreover, a collective appeal (*démarche*) has been made to the Minister of the Interior, under the leadership of the *doyen* of the Faculty of Medicine, that the exclusion of the diploma of the university should not be upheld.

---

[1] A *résumé* of the debates on the subject at the Faculty of Medicine in Paris will be found in THE LANCET of Nov. 14th, 1840.—ED. L.

March 2nd.

VIENNA.

Radium Swallowed by a Patient.

AN unpleasant incident which occurred recently in the General Hospital here caused much anxiety to the medical staff for several reasons. A woman from the country suffering from cancer of the mouth was being treated by prolonged exposure of the affected parts to the influence of radium, and for that purpose a tube containing radium was held in her mouth generally for several hours at a time. One day the tube disappeared and could not be found until the patient was examined by means of the X rays, when it was discovered in the small intestine. Apart from the fact that the valuable tube—it cost 15,000 kronen (about £600)—belonged to the hospital, there was the imminent danger of damage to the alimentary tract if the radium should act for a long time on so sensitive a structure as the intestinal mucosa. An immediate operation was therefore advised and performed, with the result that the patient now feels none the worse for her unique experience. She must have swallowed the tube in the course of a hasty meal to which she helped herself during the time of treatment, in spite of the instructions given by the medical men in whose care she was.

Munificent Donation to the Austrian Society for Cancer Research.

A generous gift of £30,000 has recently been offered to and accepted by the Austrian Society for Cancer Research. The donor, a well-known philanthropist, preferred that this large sum should be employed in practically benefiting sufferers from the disease rather than in attempts to solve scientific problems connected with the subject, and it is intended to give effect to his wishes by the establishment of a special cancer ward in the General Hospital, for which purpose another sum of over 2,000,000 kronen (about £90,000) is available already. Negotiations are at present being carried on for the purpose of enabling the society to conduct its researches in the existing wards of the Vienna hospitals until it has its own pavilion ready for occupation.

A Biological Laboratory for the University of Vienna.

There exists in our city a well-equipped biological institute which has hitherto been the private property of a few enthusiastic research workers, who have at various times published interesting reports of experiments on the variation of colours of cold-blooded animals and on symbiosis. Sometime ago Dr. Pribram and Dr. Figdor, the proprietors, presented it to the University of Vienna together with a handsome sum of money sufficient for the upkeep of the institute in perpetuity. The Vienna Academy of Science will in future control the work done there.

AUSTRALIA.

Tenth Australasian Medical Congress.

THE medical congress to be held in Auckland, N.Z., promises to be successful despite the fact that until recently shipping companies would not accept passengers on account of labour troubles. In all probability in future New Zealand will have her own organisation. The presidents of sections are:—Medicine: Dr. Sinclair Gillies, Sydney. Surgery: Mr. Hamilton Russell, Melbourne. Obstetrics: Sir D. Hardie, Brisbane. Pathology, &c.: Professor Welsh, Sydney. Ophthalmology: Dr. F. A. Pockley, Sydney. Neurology: Dr. Chisholm Ross, Sydney. Public Health: Dr. J. C. Elkington, Brisbane. Pædiatrics: Dr. P. Clubbe, Sydney. Naval and Military: Colonel C. Ryan, Melbourne. Dermatology: Dr. H. Harris, Sydney. Laryngology: Dr. R. Nolan, Sydney. A special discussion will take place on syphilis. The committee has circularised every practitioner in Australasia. In addition it has circularised all medical and social institutions, both State and private, and has information that will be embodied in a report to be laid before Congress. A review will be made of legislation in force in Australasia bearing on the subject, and the committee will bring forward its recommendations for consideration.

Neglected Children.

The annual report for Victoria states that the total number of deserted children who were a charge on the State on Dec. 31st, 1911, was 5634 and in 1912 it was 6288. The total number of deaths was 124. Of these, 88 were under 1 year old and 70 under 3 months. The medical officer states that many of these babies were in a deplorable state of ill-health and malnutrition and many were brought in a dying condition. Work under the Infant Life Protection Act was progressing satisfactorily. The system of boarding-out infants to a competent nurse, with the attendance of a medical officer always available and a trained nurse to supervise and direct, had been the means of saving many lives. There were 454 children placed in homes in this way, making 842 in all. The number of families deserted by fathers was 63, and the number of children so deserted was 149. An Act has been passed which would enable the department to reach fathers of this sort when similar legislation was adopted by the other States.

Diphtheria in Victoria.

A return of cases of diphtheria in the State of Victoria, received by the Board of Health in January, 1914, shows that 5367 cases were notified last year, compared with 5289 in 1912 and 5120 in 1911, the first year in which the greatly increased prevalence of the disease was noticeable. The spread of diphtheria during the last five years is evidenced by the fact that since 1909 the number of cases notified has increased by nearly 4000. The disease is considerably more prevalent in the country than within the metropolitan area, where there was last year a slight reduction in the number of cases compared to 1912, and a big decrease compared to the 1911 figures.

Melbourne Medical School Jubilee.

The arrangements for the celebrations are now complete. The jubilee functions will commence on Thursday, April 30th, with an inaugural ceremony in the Wilson Hall and in the evening a dinner. On Friday, May 1st, demonstrations will be given at the University and at the metropolitan hospitals, which will be continued on Saturday, May 2nd, and the celebrations will conclude with a theatre party the same evening. At a meeting of committee it was unanimously decided that a fund be established for the promotion of clinical research in the University schools. A definite resolution was worded:—

> That this meeting reaffirms the desirability of establishing a University fund for clinical research as a memorial of the jubilee of the Melbourne Medical School, and suggests to the donors that at first the interest of the fund be applied to clinical pathological research at the clinical schools.

Dr. J. W. Barrett has offered £100 per annum for five years, and Dr. R. R. Stawell, Dr. S. V. Sewell, Dr. P. S. Webster, and Mr. G. A. Syme £50 each per annum for a similar term, while numerous lesser annual sums are promised.

Health of Adelaide.

According to the city health officer's annual report the estimated city population was 42,228, which shows an increase of only 305 persons over 1912. The true death-rate was 14·42 per 1000, and the infant mortality figure is placed at 63. Twenty-three houses were condemned as unfit for habitation and 1309 notices to repair were served during the year.

Health of Brisbane.

The annual report of the Government statistician for the city of Brisbane (ten mile radius) for 1913 states that there were 5092 births and 1943 deaths, giving general rates of 35·11 and 13·40 respectively per 1000 of population. The principal causes of death were—typhoid fever, 24; measles, 35; whooping-cough, 42; diphtheria, 21; phthisis, 143; cancer, 142; apoplexy, 65. Deaths under 1 year 154. The general health of Brisbane is satisfactory, and there is nothing to show that the climate has any detrimental effect on longevity or incidence of disease.

Medical Honour.

The New Year's list of honours includes the name of Professor Harry Brookes Allen, of the Melbourne University, who was the recipient of a knighthood. Sir H. B. Allen is a graduate of Melbourne, and has been connected with the medical school for over thirty years. He was for many years professor of anatomy and pathology, but latterly resigned the chair of anatomy, which was filled by Professor R. J. A. Berry. Sir H. B. Allen has also been for many years dean of the Faculty of Medicine in the University. He has likewise filled many other positions of distinction, including President of the Eighth Australasian Medical Congress. The news of his selection for a knighthood was received with much satisfaction throughout Australia.

Jan. 27th.

THE Finsbury and Islington Medical Societies are giving a dance at Prince's Galleries, Piccadilly, W., on Wednesday, March 25th, at which all medical men and their friends will be welcome. Dancing will begin at 9.30 P.M., and tickets, price 7*s.* 6*d* (including a buffet supper), may be obtained from any member of the societies or from the honorary secretaries of the dance committee: Mr. J. N. Glaister, 96, Upper-street, Islington, N.; Mr. J. E. Jackson, 15, Huntingdon-street, Barnsbury, N.; or Mr. W. F. Roe, 12, Northampton-square, E.C.

Correspondence.

"Audi alteram partem."

THE UNIVERSITY OF LONDON: EXTERNAL STUDENTS IN THE FACULTY OF MEDICINE.

To the Editor of THE LANCET.

SIR,—The Board of the Faculty of Medicine at their meeting of Feb. 12th passed the following resolution by 7 votes to 1, I being the only member voting against it.

> That the medical degrees of the University of London should be open only to students who are students in the constituent colleges and schools of the University.

The resolution was designed to exclude the external students from the Faculty of Medicine and corroborates a similar resolution passed at a meeting of the Faculty held in 1909—a meeting when a bare quorum was present, and the vote might be regarded as a snap vote.

It will be seen that the resolution of the board out-Herods Herod, for it restricts all students of medicine to the colleges and schools of the University for the entire medical curriculum. Now the minimum time required by the regulations of the University of London for the qualifying degree is five and a half years. No other university in the world requires so long a residential qualification for any of its degrees, and it may be confidently affirmed that no other faculty in the University of London will ask for similar requirements. The avowed object of excluding the external student is to be found in the hope that by this regulation, students, now external, will be compelled to study in the schools of medicine in London, and thereby the number of students in those schools will be increased. Now 388 out of 428 members of the Faculty of Medicine are teachers in the London medical schools and incorporated colleges. An increase of students in the schools means an increase, direct or indirect, of the emoluments of the teachers. Self-interest cannot then be excluded as one of the guiding motives of the antagonism to the external student. My colleague in the representation of external students in medicine on the Senate of the University, Sir Thomas Barlow, in open Senate in fact chaffed the Deans of the Medical Schools of London for being "shopkeepers," meaning thereby that they evinced a commercial cupidity for customers—that is, students. The motive is not so pretty that one wishes to parade it naked, and so it is usually presented with some fig-leaves of clothing, in the shape of arguments more or less disguising the real reason. I propose to examine some of these arguments, and I hope to persuade the Faculty of Medicine to reverse at its next meeting the finding of the Board which, as it stands, must clearly be revised by the Faculty.

It is alleged that it is unfair to graduates of medicine who have studied in London that men who have studied elsewhere shall have the distinction of the University degree conferred upon them for passing an examination when they have not studied in the London schools. It is curious that the defence of the graduates should thus be undertaken by the Faculty, two-thirds of which, as I propose to show, are not themselves graduates of the University; whereas Convocation, which consists entirely of graduates of the University, has repeatedly opposed, and will continue to oppose, the extinction of the external students in any faculty. An analysis of the Faculty roll corrected to date, which has been obligingly furnished to me by the secretary of the Senate, reveals the following facts: (1) 337 out of a total of 428 persons—i.e., 78·7 per cent. of members of the Faculty are members of the Royal Colleges of Physicians or Surgeons; (2) 150 out of 428 persons—i.e., only 35 per cent. of the members of the Faculty—are graduates of the University.

The College qualification is in most cases taken as an adjunct to others. It is, in fact, an ornament, and, like the wearing of other ornaments, is an index to the personal preferences of the wearer. The figures at any rate show that a much larger number of persons are attracted to take the College qualifications than the University degree, and I fear it must be acknowledged that there is more affection displayed by the average man towards his University. It is therefore somewhat remarkable that the opponents of the reception of external students in the University are perfectly content to receive the external students in their own Colleges, for, of course, the examinations in the Royal Colleges are absolutely and of deliberate design external. Moreover, the universities of Oxford and Cambridge are content to examine students in the final subjects of the medical curriculum who have never attended a single lecture on those subjects in the Universities of Oxford or Cambridge. The final examinations in these Universities are therefore purely external, and these Universities are also content to give the *imprimatur* of their medical degree to students for studies which have been taken elsewhere. It has been urged in objection to this statement that the Universities of Oxford and Cambridge at least require that students for their degrees shall have passed three years at some previous time in residence at their Universities. I would point out that a separate degree, the B.A., is given for these studies, and it does not alter the truth of the statement that these Universities examine, and confer degrees, in the subjects of the final part of the curriculum without having given any instruction in these subjects to the students whom they examine. If, then, these old and illustrious foundations, the Universities of Oxford and Cambridge and the Royal Colleges in London deem it right and honourable to confer degrees upon the results of examination alone, it cannot be reasonably urged that it is not right and honourable for the University of London, which in comparison is a mere mushroom growth, to do so. Moreover, if it be unfair to give the cachet of the degree of the University of London to students who have not been taught in the London schools, it is equally unfair to deprive the students who have been so taught of the cachet of that degree, as is done in the case of students in the London schools who are taking the degrees of Oxford and Cambridge. These students are, deservedly perhaps, the special favourites of the London schools and are marked out for hospital appointments and honours; and it is singular that the Faculty who have shown themselves so anxious to create a monopoly for the London schools should be content to receive the solid emoluments derived from teaching Oxford and Cambridge students, and to be deprived of the kudos which is fairly their right for having taught these students, whose ultimate degree gives no indication whatever that they have studied in the London schools. One may adapt some famous lines to describe this curious attitude—

So careful of the fee they seem,
So careless of the honour due.

It is often stated, but the statement is erroneous, that there are at present no external students in the Faculty of Medicine. If one may use a name devised by the Royal Commissioners it may be correct to say that there are no "unattached" students in that Faculty; for, amongst other compelling facts, the regulations of the General Medical Council require that students of medicine shall pursue their studies in institutions recognised for that purpose. But these institutions are not confined to the area bounded by "a radius of 30 miles from the central office of the University" which is the statutory limit of the internal university. External students may be found within that area, but no internal students outside of it. I append a return which has been furnished to me by the officers of the University, showing the percentage of students for degrees in medicine who were classified as external in the Faculty of Medicine in the last 19 years. A consideration of this table will show that there has been no sensible diminution in the latter half of the period, when such diminution might be expected as a result of the foundation of the numerous new provincial universities which have sprung up in the last ten years. The argument, therefore, that the provincial student is sufficiently provided for and should be contented with the degree of his local university and should not presume to enter for a London degree unless he is prepared to pass five and a half years' study in the London schools seems to be unjustified by the facts, which show that the demand has remained fairly constant in the last 19 years, for which I present data. I have mentioned that the hope has been definitely expressed that some such regulation as that proposed by the Board will bring these provincial students into the London schools. I fear this hope is largely illusory, and that what will happen is that provincial students will not come to London at all, and those London teachers who are examiners

A Table Showing the Percentage of Medical Graduates Coming from Other than London Schools.

—	Total medical graduates.	M.B.	B.S.	M.S.	M.D.	Total provincial graduates.	Percentage.
1895	189	14	1	0	4	19	10·0
1896	168	9	6	0	4	19	11·3
1897	169	16	0	0	4	20	11·8

1908	191	20	0	2	5	27	14·1
1909	174	14	0	1	7	22	12·6
1910	167	14	1	0	11	26	15·5
1911	158	12	0	3	8	23	14·5
1912	141	11	0	1	6	18	12·7
1913	151	12	0	3	2	17	11·2

in the University will be thus deprived of the fees which they at present earn on account of these external students; the action of the Board of the Faculty is, in fact, comparable to that of the fabulous person who killed the goose that laid the golden eggs, which is the classical instance of insensate greed overreaching itself.

The Royal Commissioners reported against the admission of external students in the Medical Faculty, but at the same time created an overwhelmingly large and new class of students who will in reality be far more "external" to the University than any students have been in the past. If I read the regulations aright, it is contemplated that students, not being students of constituent colleges but of the so-called schools of the University, are to be examined and to be given degrees upon the results of examination by teachers who are to have merely nominal connexion with the University and are to be debarred even from sitting, as they at present do, upon the Faculty of Medicine. The control which the University will be able to exercise upon these examinations must be very shadowy, for it will be remembered that all that is required to constitute a school of the University is that the school shall admit one representative, selected by the Senate, to sit upon its governing body. At the present time the University accepts full responsibility for the choice of the syllabus and of the examiners and for the conduct of the examination; under the conditions indicated by the Commission such close supervision will no longer be exercised, and it may be as a natural corollary to this diminished supervision and control that the Commission desired to water down the responsibility of the University, which for the first time in its history is to give a degree to students whom its accredited professors and medical faculty have neither taught nor examined; and this may, indeed, explain the fantastic regulation which requires that the student shall add the name of his school to his degree. It is surprising that the teachers in those schools—and they must always form the large majority—which are not likely to be selected as constituent colleges, should not see the danger which they incur by destroying the external side of the University, towards which end the exclusion of the external student from the Faculty of Medicine is a long and important step. These schools will be in fact, if not in name, external schools, under the heel of a faculty entirely composed of their rival teachers in the constituent colleges.

The schools which are thus placed at such an unfair disadvantage cannot long survive these conditions, and are not expected by those who framed these conditions to have an existence which will be much prolonged after they come into force. Mr. Abraham Flexner, who is admittedly the chief begetter of the medical recommendations of the Royal Commissioners' report, leaves no doubt of his own opinions, which are very instructive reading in this connexion. He writes: "All work not carried on by teachers selected by the University or a university college of uncompromising academic character" (we are told elsewhere in the same report that University and King's Colleges alone in London satisfy this description) "amid conditions determined by the University, with ends set up by the University, is external work ...... in this essential sense the medical schools are external." "Ultimately," we are told, "the non-university medical school will become both superfluous and anomalous," but the kindly consolation is held out that "a useful, nay, a distinguished career" is still open to "the other hospitals" in the training of specialists and the cultivation of post-graduate studies (Carnegie Foundation for the Advancement of Teaching, Bulletin 6, chapter on Clinical Instruction in Great Britain).

It is naturally the desire of the Commission to withdraw the refuge which a strong external side as it now exists offers to the unprivileged schools, but it seems peculiarly fatuous that the schools which are likely to remain external in Mr. Flexner's sense should walk into the trap with open eyes. It surely becomes more than ever necessary to strengthen rather than weaken the defences of those schools against this new privileged class to which the Royal Commission gives such supreme power.

It will, I think, be agreed that the new "constituent colleges" will be the inheritors of the traditions and powers (the latter enormously magnified) of the present incorporated Colleges of the University, even though they may not actually be the same institutions. The incorporated Colleges have long had a preponderating influence on the present Academic Council and it will not be uninstructive to see how they have used that influence in the past; it will be an index to what the unprivileged schools may expect in the future, with the aggravation that the present checks on the action of the Academic Council will be largely removed. Professor Leonard Hill, in his minority report, handed in to the Royal Commission (Vol. II., p. 300), thus describes the present position: "The Senate has become divided roughly into two parties, a party which supports the policy of the University Colleges, and a loosely united opposition made up of those who wish to maintain the external side and the established examination test system, *and teachers who have united with this party to defend the interests of the non-incorporated schools*" (the italics are mine). Instances of this coöperation abound in the minutes of the Senate for the past eight years during which I have sat on that body, and I give three such in my own recollection.

1. In 1909 the Academic Council refused recognition of Dr. W. H. Willcox as a teacher of forensic medicine at St. Mary's Hospital. This refusal was challenged at the subsequent meeting of the Senate, and the Academic Council's action was reversed by the Senate, which was moved to mirth by the absurdity of refusing recognition in forensic medicine to the senior analyst of the Home Office. In the division list in the majority of 16 there voted 10 external representatives; in the minority of 12 there voted 8 members of the staffs of the incorporated Colleges. (Senate Minutes 1908–1909, No. 1950.) 2. In 1912 the Royal Dental Hospital applied for recognition as a school of the University in the Medical Faculty. The Academic Council vetoed the recognition, which was, however, carried against that Council at the subsequent meeting of the Senate by a combination of teachers at non-incorporated Colleges and external representatives. 3. An attempt was made by the Academic Council at the very last meeting of the Senate to restrict recognition in the Medical Faculty in future to teachers at schools of the University, a regulation which would exclude the great special-hospital schools, such as Brompton, Queen-square, Moorfields, and others. This attempt

was defeated by a combination of non-incorporated teachers and external representatives.

It may be objected that these are trivial details of recognition of teachers and schools. But this is practically the only power concerning the schools vested in the present Academic Council. Very much more important and far-reaching powers are given to the new Academic Council and Faculties, from which the teachers at unprivileged schools of the University are to be excluded. And yet these teachers are blind enough to endeavour to throw down what has been their chief bulwark in the past against aggression which will be tenfold more dangerous and rampant under the new constitution of the University.

I hope I have said sufficient to make the Faculty pause in its ill-considered efforts to abolish the external student in the Medical Faculty. He is very unlikely to be abolished in any other Faculty, and by no Faculty is the extinction of the external side of the University less to be welcomed than by the Medical Faculty.

I am, Sir, yours faithfully,
E. GRAHAM LITTLE, M.D. Lond., F.R.C.P. Lond.,
Member of the Senate of the University of London.
Wimpole street, W., Feb 25th, 1914.

"LORD LISTER: HIS LIFE AND WORK."

To the Editor of THE LANCET.

SIR,—Lord Lister once wrote that "next to the promulgation of new truth, the best thing, I conceive, that a man can do is the recantation of public error." The same, I submit, applies to a paper, and especially to a paper devoted to science. I regret, therefore, that in your review of my book upon Lord Lister you should refuse to follow this precept, and seek to throw blame upon me as giving a misleading description of THE LANCET'S one-time attitude. Your paper wrote of Mr. Lister in 1877 as being "like a man who in the excitement of enthusiasm raves at the false creations of his heat-oppressed brain," and sentences of a like bitterness, which I shall refrain from quoting. I submit that a more proper attitude on your part would have been to refrain from an attempted defence of such writing.

May I take this opportunity of expressing my regret that I did not mention the pioneer work of Sir Henry Howse. This omission was due to forgetfulness, but is without excuse in that as a student I witnessed this surgeon's faithful adherence to the teaching of the master.

I am, Sir, yours faithfully,
G. T. WRENCH, M.D. Lond.
Mussoorie, India, Feb. 9th, 1914.

*** Dr. Wrench's description in his book of the attitude of THE LANCET was inaccurate, and his quotation does not alter the fact.—ED. L.

"THE FAMILY ENCYCLOPÆDIA OF MEDICINE."

To the Editor of THE LANCET.

SIR,—I wish through the medium of your columns to express my deep regret that while I was out of town, ill, the publishers of my "Family Encyclopædia of Medicine," in an excess of zeal to make all due acknowledgment of the assistance a large number of my friends and acquaintances in the profession have given me in the way of revising and correcting special articles in the book, have advertised their names in a manner most contrary to the ethics of the profession.

It is scarcely necessary to say that both I myself and those whose assistance I have to acknowledge in my preface were quite unaware that their names were to be advertised in this fashion.

I have also taken steps to assure myself that in the future when drawing up advertisements for the "Family Encyclopædia of Medicine" the publishers will have due regard for the ethics of the medical profession. I am, Sir, yours faithfully,
HUGH H. RIDDLE.
Whiteheads grove, Chelsea, S.W., March 2nd, 1914.

To the Editor of THE LANCET.

SIR,—On the evening of the publication of the "Family Encyclopædia of Medicine" I wrote to the Amalgamated Press demanding the withdrawal of my name both from the book itself and all advertisements of it, and an apology from them for the unwarranted use of my name. The extent of my connexion with the matter is that at the personal request of Dr. Riddle I consented to look over a few pages of his MSS. and made therein a few corrections. I never at any time consented to the use of my name as an "assistant" or indeed in any way whatsoever. I am, Sir, yours faithfully,
Wimpole-street, W., March 3rd, 1914. HUGH THURSFIELD.

To the Editor of THE LANCET.

SIR,—I observe that my name appeared yesterday in the advertisement columns of the public press as having assisted in the preparation of a certain popular medical encyclopædia which is to be seen on all the railway bookstalls. I beg to inform your readers that when I promised to read the proof sheets of one section—sheets which I have not yet seen—I was under a misapprehension as to the character of the work in question. My name has been publicly advertised without my knowledge or consent. I have forbidden any further mention of it and have withdrawn my promised assistance.

I am, Sir, yours faithfully,
London Hospital, E., Feb. 27th, 1914. PAUL FILDES.

To the Editor of THE LANCET.

SIR,—On calling on a patient to-day who had had considerable experience in the advertisement of theatrical pieces she said she was lost in envy at the wide publicity secured for the professional ability of a large number of members of my profession by one of the most notable advertisements of the general public, had ever she, as a member of the general public, had ever seen. She added that she had always understood that reputable members of the medical profession avoided such a public record of their names, appointments, and qualifications. With this, she handed me a largely circulated daily paper containing the advertisement of a Family Encyclopædia of Medicine, with an imposing list in bold type of more than 30 physicians and surgeons, among whom are to be seen the name of two baronets, nine knights of one or another variety, and a goodly crop of physicians and surgeons the majority of whom are Fellows of the Colleges of Physicians and Surgeons. I enclose the advertisement for your inspection. Then follows the ingenuous remark that "It is a pleasing sign of the times that so many leaders of the medical profession should have coöperated so whole-heartedly in this notable effort to enlighten the lay public regarding the treatment and prevention of disease." An additional allurement is held forth in the fact that the work, which is published fortnightly and may be had for *7d.*, contains more than 2000 prescriptions!

I do not suggest that the more or less distinguished contributors to this philanthropic (!) publication are directly responsible for this blatant advertisement of the departments of medicine in which they practise, but I venture to think that it will be the opinion of most of the profession that the spirit, if not the letter, of the prohibition against such advertisement is infringed by their names appearing, however little on their own initiative, in this broadcast trade circular.

From time to time we find some struggling doctor accused of conduct infamous in a professional sense because he has "placed his goods in the window" in some much more obscure manner, and I fail to see that the conduct is any less infamous professionally because the goods of these more or less eminent "specialists" are placed in the window for them by someone else. Personally, I think the attention of the Censors of the Colleges should be called to this particular advertisement, and hope, Sir, that your inserting this letter in THE LANCET may have that effect. I enclose my card, and am, Sir, Yours faithfully,

Feb. 26th, 1914. F.R.C.P.

*** A meeting of the medical men concerned has been summoned, we are informed, when their course will be decided upon.—ED. L.

FRACTURE OF THE EXTERNAL MALLEOLUS.

To the Editor of THE LANCET.

SIR,—Dr. B. Whitchurch Howell asks in THE LANCET of Feb. 28th three questions in regard to the removal of the external malleolus when broken. They are easily answered:—

1. At present I only remove the malleolar fragment when it is displaced.
2. There is no sign of varus or valgus in the patients who have had the malleolus excised.
3. There is no evidence of displacement of the peronei tendons. The tendon sheaths keep them in position.

I am, Sir, yours faithfully,

JOHN BLAND-SUTTON.

Brook-street, Grosvenor-square, W., Feb. 28th, 1914.

RADIOGRAPHY OF THE SELLA TURCICA.

To the Editor of THE LANCET.

SIR,—At the last meeting of the Electro-Therapeutical Section of the Royal Society of Medicine consideration for the crowded state of the agenda list made me refrain from offering the following suggestion for centring the sella in the directly transverse rays from the tube. It will, I think, be more certain, as well as easier, than Mr. S. Gilbert Scott's shot, or Dr. Finzi's sixpences, while satisfying Dr. Parkes Weber's requirements as to giving visible evidence on the plate itself that the centring has been properly done.

Take two metal curtain rings of about 1½ inches in diameter, and to each attach two small strips of adhesive plaster. Fix them by these strips in the proper position with reference to each auditory meatus, and then arrange head and tube so that the screen shows the rings concentrically placed one apparently within the other. The central rays will then be truly transverse and unobstructed, and the shadow of the rings on the plate will prove the fact. I am, Sir, yours faithfully,

West Chapel-street, W., Feb. 24th, 1914. W. HAMPSON.

A COMPARISON OF THE ACTIONS OF CHLOROFORM AND ETHER ON THE BLOOD PRESSURE.

To the Editor of THE LANCET.

SIR,—I note in your issue of Feb. 28th a paper by Dr. H. P. Fairlie with this title in which he quotes my conclusions published in THE LANCET in 1908. He mentions that I pointed out that no form of stimulant should be given previous to or during the course of an operation. He also quotes me as stating that ether should be given as an anæsthetic. He then states that to his mind these statements are quite contradictory, for while disapproving of ether as a stimulant I recommend it as an anæsthetic "on account of the fact that it is a stimulant." Now, in my paper, I laid careful stress upon the fact that ether should not be given *because* it is a stimulant, but *in spite* of it as it is less toxic than chloroform. My actual words were: "The absence of shock is not in these cases due to any stimulating effect of the drug [ether], for, as has been pointed out, when shock is present the centres fail to react to any form of stimulant. In fact, stimulants only further exhaust the centres and aggravate the condition." I am, Sir, yours faithfully,

ALBERT J. WALTON.

Weymouth-street, W., Feb. 28th, 1914.

METHODS OF INCREASING THE ACCURACY AND DELICACY OF THE WASSERMANN REACTION.

To the Editor of THE LANCET.

SIR,—Dr. Thiele and Dr. Embleton in a paper in THE LANCET of Feb. 21st state their conclusion that "the use of cholesterin ...... in antigens for the Wassermann reaction is not only unnecessary, but introduces a very serious source of error." These authors have allowed themselves to be led into a very rash and totally erroneous generalisation. The introduction of cholesterin into syphilitic antigens was originally advocated in a paper by myself along with Dr. Cruickshank and Dr. McKenzie.[1] The statement of Dr. Thiele and Dr. Embleton as applied to our antigen, employed in the fashion which we recommended, is absolutely wrong. We showed that the introduction of cholesterin into an alcoholic solution of ox liver "lecithin" greatly enhanced the antigenic power of the latter—i.e., the property of deviating complement in the presence of syphilitic serum, but had practically no effect on the inhibitory action of the antigen either by itself or in the presence of normal serum. In addition to providing a means of increasing the antigenic power of certain lipoid solutions by means of cholesterin, we were also enabled in this way to establish a new criterion for the detection of syphilitic sera, which has proved valuable in confirming weak positive reactions. The original estimate of our method has been substantiated by nearly a dozen workers in the examination of over 3000 cases here and by other observers elsewhere. The value of the addition of cholesterin to antigens has also been shown by the procedure being adopted by such experienced workers as Sachs, McIntosh and Fildes, and Walker and Swift. With regard to the other observations of Dr. Thiele and Dr. Embleton on the effect of autolysis, the action of cholesterin by itself, &c., it may be remarked that the greater part of these results had been previously published by others, and a full account of our own work on these points and also of that done elsewhere is recorded in Browning and McKenzie's "Recent Advances in the Diagnosis and Treatment of Syphilis." I hope to have an opportunity of dealing more fully with the questions raised by Dr. Thiele and Dr. Embleton in an early issue of your journal.

I am, Sir, yours faithfully,
CARL H. BROWNING.

Laboratory of Clinical Pathology of the University and Western Infirmary, Glasgow, March 3rd, 1914.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 28th Dr. J. McIntosh and Dr. P. Fildes have criticised our paper on the "Wassermann Reaction" published in THE LANCET of Feb. 21st, 1914.

Dr. McIntosh and Dr. Fildes have entirely missed the purport of our paper and so have expressed their absolute dissent from our conclusions on a subject which they themselves have never investigated. We fully agree that the addition of cholesterin greatly increases the apparent antigenic value of an antigen and are fully cognisant of the work of Browning and Mackenzie, Sachs, and themselves. We maintain, however, that the action of cholesterin is not specific. We have shown[1] that it enhances the pre-existing anticomplementary property of some non-syphilitic sera just as it enhances the anticomplementary power which develops when a syphilitic serum is exposed to an antigen. This is the point that Dr. McIntosh and Dr. Fildes have failed to deal with in their papers. We do not deny that the use of cholesterin with an alcoholic heart antigen, or a weak lecithin antigen, greatly increases the sharpness of the reading, and has shown up cases which would otherwise have been missed, but this addition is only necessary when the true antigenic power of the antigen is weak—in fact, the addition of cholesterin is the confession of a weak antigen.

By the method of Dr. McIntosh and Dr. Fildes the true antigenic value of the antigen is never ascertained.[2] It is taken for granted. It does not necessarily follow that the different samples of antigens obtained by their method are of constant value; in fact, it has been shown by Noguchi and ourselves that even with a uniform technique the antigenic value of the extracts from the same type of organ is not constant. By our method[3] we can always rely on getting an antigen which is so powerfully antigenic that it requires no aid from cholesterin to show the complement fixation that has occurred; it is not anticomplementary, so that large amounts can be used, and it is not hæmolytic.

With regard to our statement that the Wassermann reaction as ordinarily performed is apt to give erroneous results with corpse sera, &c., we should just like to draw attention to the latest communication appearing in connexion with this by Boas and Eiken.[4] These observers examined 540 corpse sera, and using 200 c.mm. of the sera they obtained so many positive results that they regarded the test as useless; using 100 c.mm. of serum they obtained negative results in 17 per cent. of cases where there was active untreated syphilis.

Lubarsch[5] out of 109 corpse sera which gave a positive Wassermann reaction had 41 which were from non-syphilitic cases, these latter forming 7·3 per cent. of the total number of sera examined. M. Rabinowitch,[6] examining 3000 normal sera found that when stored all would give a positive Wassermann reaction, thus showing that all sera when they become anticomplementary can give a positive reaction with an anticomplementary antigen. Fildes[7] also reported 15 per cent. of positive reactions in corpse sera.

In conclusion, we have brought forward a powerful antigenic substance, so powerful that three-millionths of a gramme will give complete fixation in the Wassermann reaction. This antigen is easily obtainable and quite stable, and has no interfering anticomplementary or hæmolytic factors. We hold that it is absolutely unnecessary to use cholesterin antigens when such a powerful non-anticomplementary antigen can be obtained. These cholesterin antigens may give rise to a source of error in that occasionally a normal person may be diagnosed as syphilitic.

We are, Sir, yours faithfully,
FRANCIS H. THIELE.
DENNIS EMBLETON.

ASSOCIATION OF ASSISTANT MEDICAL OFFICERS OF ASYLUMS, ENGLAND AND WALES.

To the Editor of THE LANCET.

SIR,—I shall be much obliged if you can find space in your next issue to publish the fact that the first annual general meeting of the above association will be held at the Westminster Palace Hotel, London, on Saturday, March 14th, 1914, at 3.15 P.M.

I am, Sir, yours faithfully,
F. J. STUART,
Honorary Secretary.

Berry Wood, Northampton, March 1st, 1914.

THE TREATMENT OF COLI-CYSTITIS BY FLUID ELECTROLYSIS.

To the Editor of THE LANCET.

SIR,—Since the appearance of my paper in THE LANCET of Feb. 14th I have been informed of the work of Professor E. W. Ainley Walker and Dr. Murray[1] on the lengthening and other characters induced in typhoid and colon bacilli by their cultivation in media containing aniline dyes. There is also another work, by G. Dreyer, S. G. Scott, and E. W. A. Walker, dealing with an induced change to Gram's stain of various bacteria after treating them with different chemical substances.[2] These researches are of great interest and value. They would have been included in my paper if the means of altering bacterial characters had been its subject. Nevertheless, priority of observation that such new characters can be induced in bacteria is on similar lines, rather than in the manner suggested by Mr. Parker.

Visions, unfortunately, do stimulate public opinion, and public opinion can give rise to Governments that may be good or bad; so that a time may come when statesmen of the type of Keir Hardie and Will Thorne may rule our political system; then, in a Socialist state, medicine, together with every other art and science, will have to submit to the reign of Collectivism. Many of us, however, congratulate ourselves that we shall probably not live to witness the experiment.

I am, Sir, yours faithfully,

Hackney-road, N.E., March 1st, 1914. MAJOR GREENWOOD.

WHAT IS CHAULMOOGRA OIL?

To the Editor of THE LANCET.

SIR,—In view of the renewed interest which is being taken in chaulmoogra oil and "antileprol" (an extra refined form of chaulmoogra oil) as a curative or alleviative in leprosy, it is important to draw the attention of the medical profession, superintendents of leper asylums, governments, and the drug trade to the fact that nearly all the so-called "chaulmoogra oil" upon the European market is spurious or adulterated. The true chaulmoogra oil is expressed from the seeds of Taraktogenos kurzii. In 1912 the crop of Taraktogenos kurzii seeds failed almost completely. Some firms of chemists, being unable to forego the temptation of high profits, began in 1913 to ship the oil obtained from seeds of Hydnocarpus wightiana as "pure chaulmoogra oil."

Nearly all the large European druggists were deceived; there is practically no genuine chaulmoogra oil at present on the European market, nor has there been for the past 18 months. Very large quantities of spurious oil have been imported and retailed, and many leading firms have been victimised. The substitute, Hydnocarpus wightiana, is similar in composition and appearance. It, however, has little therapeutical value in leprosy, and its cost in India is about one-third that of the true oil (Taraktogenos kurzii).

I have drawn the attention of Sir Malcolm Morris, who is now in India, to the facts, and also that of the Colonial Office. I have forwarded specimens of the true and false oils to Mr. Martindale, Mr. Parry, and Mr. Squire, and to most of the firms concerned. That some of these firms do not recognise the gravity of the fraud upon a particularly hopeless people like lepers is obvious from the letters which I have received. One Indian firm, while admitting that their oil is probably from the Hydnocarpus, announce their intention of continuing to sell it as "guaranteed pure."

The Taraktogenos kurzii tree occurs only in the Chittagong Hill tracts, Burma, and parts of Assam. The Governments of Bengal, Burma, and Assam have leased out the *sole* right of collection of these seeds in the forests concerned to a company whose representatives in London are Messrs. Bulloch Brothers and Co., Limited, of 13, Fenchurch-avenue, E.C. Leper asylums and Governments and all charitable institutions can obtain from them pure cold-drawn chaulmoogra oil (expressed from seeds of Taraktogenos kurzii) at a very cheap rate.

I am, Sir, yours faithfully,

ERNEST E. FRANCIS, M.R.C.S. Eng., L.S.A. Lond.,
Chief Medical Officer, Assam-Bengal Railway.

⁂ Mr. Francis encloses copies of the correspondence which has ensued upon his making representations to various firms of chemists and druggists.—ED. L.

THE NATIONAL INSURANCE ACT.

THE DEPARTMENTAL COMMITTEE ON ALLEGED EXCESSIVE SICKNESS CLAIMS.

THE Departmental Committee on Alleged Excessive Sickness Claims having asked that evidence might be submitted to it on behalf of the London Insurance Committee, that body on Feb. 26th appointed its chairman (Mr. J. A. Dawes, M.P.) to give evidence, and approved a draft statement of its views. In regard to the work of the medical referees, the committee decided to express the opinion that it was not necessary for insured persons to have the right of appeal to the referees against the opinion of their doctor, because the case of an insured person who had been refused a certificate by his own doctor was so dubious as not to justify the right of access to a medical referee. In the case of the medical practitioner, however, the committee thought there should be such right of access. Although no formal representations had been made on this point by bodies representing the profession, a large number of communications had been received from individual practitioners asking for the right of access to the referee. It was a matter for consideration whether the action of Approved Societies in referring cases to the medical referee without consulting the panel practitioner did not tend to create resentment on the part of the practitioner. The question of the incapacity of an insured person in the case of an Approved Society appeared to take the form of whether a certificate furnished by a medical practitioner should be accepted without question. It had not always been easy to appreciate the reason given by an Approved Society for doubting the accuracy of a medical certificate. In a large number of cases the reason advanced had been either "prolonged duration of illness" or "question of total incapacity." If the practitioner had been approached first he would doubtless have supported his certificate with further information. The desirability of the Approved Society first consulting the panel practitioner was particularly apparent in cases where the only reason for the society referring the case to the referee had been that a lay "sick visitor" had doubted the practitioner's certificate. A *bonâ fide* reason should be required of an Approved Society for referring an insured person to the referee. The committee further expressed the opinion that the appointment of referees should continue to be made by the Insurance Committee in order that records might be classified and greater uniformity be secured in the issue and acceptance of certificates. The committee decided to place before the Departmental Committee a number of statistics from which we take the following items; the figures relate to the period ended Jan. 11th, 1914:—

The number of doctors on the panel	1475
The number of doctors in the area in general industrial practice who are not on the panel	500
The greatest number of insured persons on any individual doctor's list (the doctor has since taken a partner)	5177
The average number of insured persons on the lists of all the doctors	909
The number of doctors (including practitioners in partnership) who had on their list—	
(*a*) Less than 500 insured persons	500
(*b*) Between 500 and 1000	261
(*c*) Between 1000 and 1500...	189
(*d*) Between 1500 and 2000	151
(*e*) Between 2000 and 2500	84
(*f*) Between 2500 and 3000	60
(*g*) Over 3000	48

The number of insured persons—	
(a) Who failed to select a method of treatment (approximately)	228,000
(b) Who elected to receive treatment through an approved institution	3233
(c) Who were allowed to make their own arrangements ...	1549
The number of cases of change of doctor by consent during the year (approximately)	7480
The number of cases of change of doctor at the end of the year	12,439

Some discussion took place as to the accuracy of the estimate of 500 as the number of doctors in general industrial practice who were not on the panel, and it was generally agreed that 1000 would be a more accurate figure.

HOSPITALS AND THE NATIONAL INSURANCE ACT.

At this time of the year, when throughout the country balance-sheets for 1913 and estimates of liability for 1914 are coming under consideration, it is natural to find comment upon the effect which the Act is believed to have upon hospital finance. The past financial position is considered and the future surmised. At the recent annual dinner of the Hospital Saturday Fund reference to the effect of the Act was made by the Chairman, by Sir Savile Crossley, and by Sir Reginald Acland in speeches which attributed a falling off of income, in part at least, to the operation of the Act, though the speakers were able to maintain a hopeful attitude with regard to the future. At the annual meeting of the qualified contributors to the Glasgow Royal Infirmary Lord Provost Stevenson, who presided and moved the adoption of the report, referred to the effect of the Act in reducing the number of out-patients, but stated that the number of serious cases treated in the infirmary was being more than maintained. The number of out-patients had been reduced by about one-third, which corresponded to the estimated number being treated under the Act: and as the honorary staff of the hospital, who were treating the remainder, had not been diminished in number, the patients must be receiving fuller attention. He commented upon the unfairness of medical men on the panel sending to the infirmary patients whom they should treat themselves, but expressed no anxiety as to the financial position of the infirmary. which appeared to be satisfactory. At Bootle, at the annual meeting of subscribers to the Borough Hospital, reference was made to the difficulty experienced in educating insured persons to have recourse to medical men on the panel instead of going to the hospital as they were accustomed to do. The hospital had suffered considerable loss of income, which was attributed, in part at least, to the stoppage of weekly collections among working men now called upon to pay their quota under the Insurance Act. The committee desired to refute the idea expressed by some that the need for the hospital was lessened by the Insurance Act. At the annual meeting of the subscribers to the Ayr County Hospital, the report submitted showed that the number of patients treated at the dispensary was 383, a decrease of 683. The number of operations performed in the hospital was 936, as against 604 in 1912, a very large increase which was ascribed to the effect of the Insurance Act, as was also a decrease of £142 in the income derived from subscriptions. It may also be noted that under the recently proved will of Mr. John Shiel, of Newcastle-on-Tyne, chairman of two colliery companies and director of a coal and coke company, a legacy of £1000 had been left to the Harrogate Convalescent Home connected with the Durham County Hospital. This bequest was revoked "in view of the provisions under the Insurance Bill and sanatoria provided thereby." It is to be hoped that no testators will allow the benevolent disposition of their property to be affected by any mistaken idea that the utility of hospitals has been put an end to or their needs diminished by the Act, which tends more and more to have an exactly contrary effect.

THE MEDICAL RESEARCH COMMITTEE.

Regulations were issued on Wednesday last for the guidance of the Medical Research Committee, the constitution of which, under Lord Moulton of Bank as chairman, will be found in an article in THE LANCET of Sept. 27th, 1913, p. 970. In the same article the *personnel* is given of the Advisory Council, over which Lord Moulton also presides. The new Regulations provide that the committee should from time to time prepare schemes for research for submission to the Chairman of the National Health Insurance Joint Committee, who will take the advice thereon of the Advisory Council.

LOCAL MEDICAL COMMITTEE FOR LONDON.

The Metropolitan Counties Branch of the British Medical Association has undertaken the duty of arranging for the election of the long-deferred statutory Local Medical Committee for the County of London. The scheme of election is briefly as follows. The committee will consist of 60 members with representation for medical men on the panel, for medical men not on the panel, for members of hospital staffs, for the public health and Poor-law medical services, and for medical women. The representation for medical men on and off the panel has been calculated from the estimated number of practitioners. The election will be carried out by postal vote. One panel representative will be elected for each of the 29 boroughs of London, while with the exception of Marylebone, which has a representative to itself, the boroughs will be arranged in groups for the election of 22 non-panel representatives. Nominations and votes to be valid must come from those actually residing in the particular borough or group of boroughs, but there will be no restriction as to the residence of candidates nominated. The six representatives of the medical staffs of hospitals will be elected by the members of the permanent staffs of hospitals resident in London; while one medical officer of health, one Poor-law medical officer, and one medical woman will be nominated and elected respectively by the metropolitan branch of the Society of Medical Officers of Health, the Poor-law Medical Officers' Association, and the Association of Registered Medical Women.

LONDON MEDICAL BENEFIT SUBCOMMITTEE.

This committee recommends with regard to the allocation of funds arising in respect of insured persons not assigned to or accepted by medical men on the panel, that practitioners having more than 2000 patients on their lists shall not be credited with further fees in respect of the number of patients on their lists above 2000, but that the fees to be divided shall be apportioned among practitioners on the panel in proportion to the numbers not exceeding 2000 on their lists. Medical practitioners who have modified the conditions of their agreements so as formally to limit their lists given by Mr. WEDGWOOD BENN. Without this explanation the reported proceedings of Parliament might give rise to some confusion as to the identity of the Ministers who are undertaking the Parliamentary representation of the National Insurance Commissioners.

Medical Attendance on Insured Persons.

A return which Mr. WORTHINGTON EVANS has asked for in regard to medical attendance under the National Insurance Act has been refused by the Government. What the honourable Member asked was particulars as to the number of insured persons who at the end of the first year after the National Insurance Act came into operation had chosen panel doctors, the number who had chosen an approved institution, the number who had been assigned by the several Insurance Committees to panel doctors or to institutions, the number who had been allowed to make their own arrangements for medical treatment with doctors not on the panel, and the number who had neither chosen doctors nor institutions nor had been assigned to doctors nor had made their own arrangements. Mr. WEDGWOOD BENN, in declining to grant the return, expresses the opinion that it would not be of a public utility sufficient to justify the time and labour necessary for its compilation and for ensuring its accuracy.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 25TH.

Deposit Contributors and Medical Benefit.

Replying to Mr. MACCALLUM SCOTT, Mr. WEDGWOOD BENN said: A deposit contributor is only entitled to such benefits as can be provided from the amount standing to his credit in the deposit contributor's fund (including the moneys provided by Parliament). It follows, therefore, that when a deposit contributor has passed the age of 70, and further contributions are not payable in respect of him, he will not be entitled to medical benefit after the sum standing to his credit has been exhausted.

Complaints by Gloucester Panel Practitioners.

Mr. G. LOCKER-LAMPSON asked the Secretary to the Treasury whether complaints had been made by Gloucester panel doctors that certain Approved Societies had failed to supply forms for medical certificates and had ignored requests for such forms; whether insured persons' benefits were thereby in danger of disturbance, refusal, or delay; and what the Government proposed to do in the matter.—Mr. WEDGWOOD BENN replied: The matter referred to had not previously been brought to the notice of my right honourable friend, but he is in communication with the Insurance Committee and the Approved Societies concerned.

Medical Certificates and Sick Pay.

Mr. G. LOCKER-LAMPSON asked the President of the Local Government Board whether his attention had been called to the case of a member of an Approved Society who entered the Marylebone Poor-law infirmary on Jan. 12th last, remaining there three weeks, and who was unable to get sick pay from his Approved Society because the society would pay only on the production of the doctor's certificate and the infirmary doctor and authorities refused to give one; and whether any pressure could be brought to bear either upon the Approved Society or the infirmary officials so that this man might obtain his rights.—Mr. HERBERT SAMUEL answered: My attention had not been previously drawn to this case. It is the duty of the medical officer of the infirmary under the Local Government Board's regulations to give a certificate to the person on whom he is attending of the sickness of such person or the cause of his attendance on him, and I am calling the attention of the guardians to this requirement.

Selection of Medical Men.

Mr. WEDGWOOD BENN informed Mr. WORTHINGTON-EVANS that information was not available how many insured persons had not selected a medical man for the purpose of the National Insurance Acts at the end of the first insurance year, or in how many cases doctors had been assigned to insured persons by Insurance Committees before that date. The information could not be obtained without a special return from all Insurance Committees in Great Britain. If the honourable Member would put down a motion for a return the matter would be considered.

Accommodation for Tuberculous Persons.

Mr. G. LOCKER-LAMPSON asked the Secretary to the Treasury whether his attention had been called to the conference of Poor-law authorities on Feb. 18th last, where it was stated that such authorities had spare accommodation for tuberculous persons; and whether, in view of the fact that there was still a shortage of accommodation for insured tuberculous persons which was causing delay in their treatment, he would do his best to effect a temporary arrangement similar to that in connexion with the Metropolitan Asylums Board, so that such spare accommodation might be utilised for them.—Mr. WEDGWOOD BENN said in reply: It is not open to Insurance Committees to [illegible] the treatment of insured persons by [illegible] The case of the Metropolitan Asylums Board is governed, as the honourable Member knows, by special provisions in the 1913 Act.

Reorganisation of London University.

Sir PHILIP MAGNUS asked the Prime Minister whether the Government intended to introduce this session a Bill for the reorganisation of the University of London, in general accordance with the recommendations of the Royal Commission on University Education in London, and, if so, whether that Bill would be presented as a separate measure, or as part of the measure for the development of a national system of education, to which reference was made in the gracious speech from the Throne.—Mr. ASQUITH answered: Pending the report of the Departmental Committee on the University of London, I am not in a position to announce the intentions of the Government. It will probably be convenient and desirable to deal with this question in a separate measure.

Declarations under the Vaccination Act.

Mr. W. HARVEY asked the Home Secretary whether his attention had been called to the fact that in some parts of the country conscientious objectors under the Vaccination Act, 1907, experienced great difficulty in finding a justice of the peace who was willing to witness their declaration; and whether he was prepared either to take steps to compel all magistrates to sign exemption orders or else provide additional facilities for those who desired to avail themselves of the exemption afforded by the Act.—Mr. MCKENNA replied: One or two complaints of this sort have been received, but I have no reason to think that the difficulty is of frequent occurrence. If my honourable friend will let me know of any particular cases where magistrates have refused to take the declarations I will make inquiry, but he should understand that I have no authority to compel them to do so, and I fear I could not undertake to propose legislation on the subject at the present time.

Medical Men and the National Insurance Act.

During the course of the debate on the motion in favour of an inquiry into the working of the National Insurance Act, Mr. LLOYD GEORGE expressed his opposition to the establishment of a voluntary system in place of the present compulsory system. In the course of his speech the right honourable gentleman said that one honourable Member complained that in 18 months all the sanatoria had not been erected. Another honourable gentleman said that sites were actually being bought. How could sanatoria be built without sites? A sum of £1,600,000 had been set aside for the purpose.

An honourable Member: Has it been spent?

Mr. LLOYD GEORGE replied that it had not been spent because all these places could not be built in 18 months. The £1,600,000 was an offer made by the State to meet local expenditure. It was an offer not of £1 for £1. 60 per cent. of the expenditure was offered as a grant from the Exchequer. Wherever the local authority had come forward—and he was glad to say that these authorities had come forward in his part of the country—and offered to build, the State had been ready to provide 60 per cent. of the total expenditure. But it was impossible to purchase sites and build sanatoria in 18 months. Speaking of the difficulties which had been experienced in bringing the Act into operation the right honourable gentleman said that there was some difficulty with the doctors at first. The doctors came in for the moment somewhat sulkily in some parts of the country, but the testimony which he had received from every part now was that the doctors were working, not merely freely, but heartily and well. There might be one or two cases where that was not so. From some societies in different parts of the country he had complaints, but in the main the doctors were working with a will. To rush to conclusions after the first year of administration, when the machinery had not been properly organised and systematised, would be folly on the part of the Government, but to come to the conclusion that they should make alterations which would be permanent, on the purely temporary basis of the experience which they had had, was a policy which no Government could adopt without possibly incurring expenditure of a very extravagant character.

THURSDAY, FEB. 26TH.

No State Medical Service.

Mr. G. LOCKER-LAMPSON asked the Secretary to the Treasury whether a Government committee was at present considering the subject of a State Medical Service, and was actually preparing plans for such a scheme.—Mr. WEDGWOOD BENN replied: No, sir.

Domiciliary Treatment of Tuberculous Persons.

Mr. G. LOCKER-LAMPSON asked the Secretary to the Treasury whether his attention had now been drawn to the tatement in the report of a subcommittee of the West Ham

Insurance Committee that out of 95 tuberculous persons receiving domiciliary treatment in their area at the end of 1913, no less than 37 were sleeping in the same rooms as other persons; and what the Government proposed to do in the matter.—Mr. WEDGWOOD BENN replied: It is the duty of the committee to arrange for the provision of treatment [illegible] recovery, but they have no means of enforcing those instructions in such cases as those referred to in the question except by making their observance a condition of the receipt of treatment, which would in many cases deprive the insured person for causes beyond his control of all the benefit of treatment.

The Drug Fund in Manchester.

Mr. G. LOCKER-LAMPSON asked the Prime Minister whether, in view of the anxiety felt by panel chemists in Manchester owing to the deficiency in the drug fund in that district under the National Insurance Act and the non-payment of a large portion of their accounts for 1913, he would give a pledge on behalf of the Government that they would all be paid in full.—Mr. ASQUITH answered: No question arises for such an undertaking as that asked for in the question. The amount of the remuneration payable to the Manchester panel chemists is governed by the contracts into which they have entered with the Manchester Insurance Committee, and they will receive the whole of the sums due to them under these contracts.

Mr. LOCKER-LAMPSON: Is it not a fact that these chemists are not in the least responsible for the nature of the prescriptions ordered by the doctors?—Mr. ASQUITH: I would ask the honourable Member to put that question down on the paper.

Sir W. P. BYLES: Is the honourable gentleman (Mr. Wedgwood [illegible] the Manchester and Salford [illegible] ally £1600—[Mr. LOCKER-LA[illegible] oney which they earned during last year? What I want to know is whether they have to lose that money?—Mr. WEDGWOOD BENN: My right honourable friend is aware that a joint committee of doctors and chemists are going through the accounts.

The Vaccination Laws.

Mr. BRIDGEMAN asked the President of the Local Government Board whether he would state how many resolutions he had received from Poor-law unions stating that the present system wa[illegible] laws and asking for [illegible] science clause; and [illegible] to meet their wish [illegible] answer to the first [illegible] the second part of [illegible] Member to my re[illegible] occasion.

Criminal Lunatics.

Mr. TOUCHE asked the Home Secretary whether persons confined in criminal lunatic asylums were allowed to see [illegible] ote in [illegible] legal [illegible] er the [illegible] and a [illegible] d not [illegible] The [illegible] tions) [illegible] times [illegible] opped [illegible] etion [illegible] rge of lunatics to decide when [illegible] gulations could be laid down [illegible] which render such a course [illegible] require all letters so stopped [illegible] l supervision of the asylum at [illegible]

MONDAY, MARCH 2ND.

The Prevention of Shuttle-kissing.

Replying to Major STANLEY, Mr. MCKENNA (the Home Secretary) said: The inspectors of factories have for some [illegible] last conference in October a [illegible] the three parties was appointe[illegible] cotton mills of various device[illegible] ceeding, and I am not in a position to make any definite statement at present, but I have good hope of their leading to a satisfactory result.

The Solvency of Approved Societies.

Mr. BONAR LAW asked the Chancellor of the Exchequer whether or not it was the case that on the evidence now available the chief actuary had reason to consider that a large number of Approved Societies would on valuation be unable [illegible] in respect of men's societies generally has been well within the actuarial expectations. The experience in respect of women, however, indicates some excessive sickness benefit expenditure, and this excess arises particularly from the claims in respect of married women. There are also considerations affecting some societies having an undue proportion of members in specially unhealthy trades. A strong Departmental Committee is now examining the whole subject, and I hope that its report and evidence will be helpful in the consideration of how best to meet the particular difficulties.

TUESDAY, MARCH 3RD.

Nurses' Registration Bill.

Dr. CHAPPLE, in moving for leave to introduce a Bill "to regulate the qualifications of trained nurses and to provide for their registration," said that the Bill proposed without compulsion and without cost to the State to set up a nursing council. That council would be charged as part of its duty to prescribe a curriculum and also a minimum standard of training for nurses. It also provided for certificates being granted to those nurses who passed the examination prescribed by the Council. It was [illegible] t. Any woman would [illegible] she practised it now. [illegible] woman would not be [illegible] had been trained at [illegible] e. The matter would [illegible] tioners. [illegible] was quite [illegible] circularise [illegible] nurses. [illegible] imposed u[illegible] of untrain[illegible] had been [illegible] The head [illegible] Hospital. [illegible] which op[illegible] hospital which exploited nurses for its own financial advantage. It gave certificates to nurses at the end of two years, whereas it was recognised by other hospitals that three years was a necessary curriculum.

Mr. BOOTH said that the references to the London Hospital alone would entitle honourable Members by way of protest to vote against the motion. It was doing a great work amongst the poor in the East End. He also pointed out that the standard for registration was not agreed.

By 311 votes to 82 leave was granted to bring in the Bill.

Dr. CHAPPLE formally introduced the Bill, which was read a first time.

WEDNESDAY, MARCH 4TH.

Manchester Panel Chemists and Prescriptions.

Mr. GODFREY LOCKER-LAMPSON asked the Secretary to the Treasury whether the Manchester panel chemists had any control over the nature of the prescriptions ordered by the doctors; and, if not, why they should not be entitled to full payment fo[illegible] up.—Mr. WEDGWOOD BENN [illegible] first part of the question is [illegible] Regulations it is open to the [illegible] y area to obtain a scrutiny of [illegible] by them, with a view to sure [illegible] s responsible with the cost of those shown to be excessive or extravagant.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE MILWARD FUND.

Mr. William Courtenay Milward, B.A. Oxon., M.R.C.S., L.R.C.P., of Cardiff, died on April 9th, 1913, leaving a widow and three boys, aged 15, 9, and 2. His estate produced £200, to which is to be added £163 collected from the local profession as a testimonial to Mr. Milward shortly before his death. This fund, for the benefit of the widow and children, was opened on April 15th, 1913, and closed on Jan. 31st, 1914. The total amount collected from medical men and a few non-medical friends with bank interest is £1348 11s. 1d. The expenses of collection were £20 5s. 2d., leaving £1328 5s. 11d. Besides this sum promises of further annual subscriptions to the fund will bring in the following amounts, viz.:—

In 1914	£56 5s.
,, 1915	£56 5s.
,, 1916	£51 5s.
,, 1917	£44 19s.
,, 1918	£36 12s.

We hope to publish the statement of the committee of the fund in an early issue of The Lancet.

MARTIAL AND MEDICINE.

To the Editor of The Lancet.

Sir,—Owing to absence in Spain I have only to-day seen Mr. Eade's letter of Feb. 18th on this subject in your issue of Feb. 21st. I was familiar with the epigram, "Lotus nobiscum est," &c., but I refrained from translating it, as I felt I could not cut myself free from a spirited rendering which I had read in some old Dublin magazine, and which I fancy I recollect correctly as follows:—

[illegible] was well and hearty,
[illegible] mer party:
[illegible] was the attack?
[illegible] the quack.

In the absence of any books of reference, I speak hesitatingly as to Mr. Platt's suggestion that Martial was indebted to Lucilius for his jibe. The two men were contemporary, and though Martial published his poems mainly towards the end of the first century A.D., I cannot be sure which wrote before or after the other.

A few days since I passed through the place of Martial's birth, the ancient Bilbilis. The whole district is a congeries of wild craggy mountain sides. The low houses, mostly of one storey and built of the local stone, seemed welded into the brown rock on and in which they are built. So alike in colour are houses and rocks that a whole town, right before your eyes, only slowly emerges out of the dreary dun background. One cannot wonder that Martial sighed for the flesh-pots of Imperial Rome.

I am, Sir, yours faithfully,
Nimes, March 2nd, 1914. Raymond Crawfurd, M.D.Oxon.

GRENADA MEDICAL REPORT.

The Blue Book report of Grenada for the year 1912, which the Governor explains has been delayed by various causes, estimates the population of the colony at 68,485. The birth-rate per 1000 was 38·19 and the death-rate 22·9. The year was not a healthy one, the death roll reaching 1575, whic[illegible] for Grenada. Diarrhœa, dysentery, and [illegible] the principal causes of death, and there were no less than 76 deaths from phthisis recorded. The rainfall at Richmond Hill station, 63·98 inches, was the smallest recorded since 1900, when it was 63·45 inches. The average rainfall at this station for the last 22 years has been 76·98 inches. A case of bubonic plague was introduced from Trinidad, but fortunately the subject was under suspicion from the moment he arrived and was removed from the ship to the isolation hospital, where he died. A most important change affecting the health of the lower class [illegible] during the year, the fees of medi[illegible] "labourers" being considerably [illegible] 'labourers'" medicine altered from 1s. to 6d. per prescription. It has thus become possible for a labourer in Grenada to go to the residence or station of a district medical officer and obtain medical advice and medicine for 1s. 6d., while the fees for visits to patients' houses have [illegible] reduced.

In the colo[illegible]nts were treated during the year, in[illegible] from ankylostomiasis. This hospital has been much improved and its work expanded. An English nurse matron, Miss J. S. Gardner, has been appointed, and accommodation provided for

36 more patie [illegible] constructed [illegible] In the Yaws [illegible] charged as c [illegible] treatment of the disease by salvarsan was carried out with [illegible] pensary, which [illegible] which 7205 were [illegible] pital the number of patients treated was only 186, of whom 129 were cured, 22 relieved, and 7 died. A much-needed hospital for consumptives has been opened, providing accommodation and treatment on modern lines for 24 cases.

THE "ART AND MYSTERY" OF MEDICINE.

To the Editor of THE LANCET.

SIR,—From time to time I re [illegible] longer a "mystery." I [illegible] on this fact is based on a [illegible] stery meaning a secret doctrine has quite a different etymology to mystery, a trade, profession, or handicraft. The latter is seen in the old French *mestier* [illegible] that medicine [illegible] ministration [illegible] is almost equ [illegible] medicine," and any arguments based on a false etymology fall to the ground. I am, Sir, yours faithfully,

London, March 3rd, 1914. BLANCUS.

A BY-LAW CONCERNING HATPINS AT CARDIFF.

IT is probable that the Cardiff corporation is the first public body in the United Kingdom to decide to take steps to lessen the danger from the pointed ends of hatpins protruding from the hat of a lady. On the proposition of a medical member of the corporation a by-law has been passed to the effect that—

> A female person wearing a hatpin in any street or public place, church, chapel, or other place of public worship, public hall, public waiting room, place of public entertainment, or public carriage shall cause the point to be properly protected by a blunt guard of metallic or other material.

AN ELASTIC TRUSS.

Mr. John Dee Shapland, of Exmouth, has sent us a new form of truss which he has found very useful in practice. It is almost impossible for anyone to devise a truss on an entirely new principle, [illegible] details than on the mer [illegible] are no metal springs [illegible] rubber exterior filled [illegible] to bear on the ingui [illegible] rigid as in many for [illegible] position by means of [illegible] to be of great value [illegible] geons know that in one case one form of truss suits a patient well, while in another case a different form is needed; there is no truss which will fit all forms of inguinal hernia, but this truss is well designed and deserves to be tried in any case in which the ordinary forms have failed to retain the hernia.

INSURANCE AGAINST TWINS.

A p [illegible] it will in [illegible] whom ar [illegible] editor proposes to give £5 to every mother of twins born in the United Kingdom, the Channel Islands, and the Isle of Man during the month of July next, on condition that readers who claim the bounty shall retain the 12 coupons to be issued with the paper during the 12 previous weeks. [illegible] £5 must be sent in within [illegible] ccompanied by the 12 coupons [illegible] medical man or certified [illegible] oth children have lived for [illegible] of the editor is final. What [illegible] receives a letter five weeks [illegible] child to say that a second child has been born to the mother? Such a case actually did happen last year at Barrow, near Clitheroe, when the father made application for maternity benefit in respect of the second child. The Commissioners decided that it was a separate birth, thus entitling parents to the double benefit (*vide* THE LANCET, June 7th, 1913, p. 1627), but it might be argued [illegible] not constitute twins. As [illegible] which will be claimed, Dub [illegible] ouchements in Germany, En [illegible] e 6248 cases of twins, 78 of triplets, and 4 of four at a birth, or putting it in another form there was one case of twins in 78 *deliveries, one case of triplets* in every 6209 deliveries, and one case of four at a birth in 121,082 deliveries. Veit, basing his statement on an immense number of deliveries, found the proportion of one twin delivery to 89 single births. In France twins are delivered in the proportion of 1 to 92 single births, in Germany 1 to 84 cases, and in Great Britain 1 to 63 cases of single births.

HOW DISEASE IS SPREAD.

AT the last meeting of the Totnes (Devon) rural district council the medical officer of health (Mr. S. C. Jellicoe) reported two cases of diphtheria in the village of South Brent. He stated that in each case printed and verbal instructions were given as to the precautions required to be taken, but in the case that terminated fatally these were absolutely unheeded, and nearly 20 school children were allowed to enter the house and touch the dead child's body.

THE "TANTLUS" BOTTLE LOCK CORK.

WE have received from Mr. H. Yeild Collis, of 4, Market street, Stourbridge, a [illegible] invented for locking [illegible] Its working principle [illegible] to the inventor tha [illegible] advantage to poison [illegible] *of the cork is fitted* [illegible] its end. The bolt can only be released by a key. When it is released it resembles a buffer of a railway carriage. When it is pressed down again on the corks it automatically locks, and neither corkscrew, lever, nor fingers can extract the cork, which is well sunk into the neck of the bottle. The act of pressing the key [illegible] moderate. The fact that a key is required to release a cork draws attention at once to the serious nature of the contents of a poison bottle.

Mr. H. Hacs.—There is nothing in our correspondent's suggestion.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced. In 1914:—

April 13th and 14th (Berlin).—Thirteenth Congress of the German Orthopædic Society.

" 13th-16th (New York).—Fourth Congress of the International Surgical Society. (President: Prof. Depage, Bruxelles.)

" 15th-18th (Berlin).—Forty third Congress of the German Surgical Society.

" 19th-21st (Berlin).—"Jubilee" Congress of the German Röntgen Society.

" 20th-23rd (Wiesbaden).—Thirty-first German Congress for Internal Medicine.

" 27th-May 1st (London, Royal Horticultural Hall).—Nursing Conference and Exhibition.

May 1st-Nov. 1st (Lyons).—International Town Hygiene Exhibition.

May-October (London, Shepherd's Bush).—Anglo-American Exposition.

June 18th-24th (London, Church House, Westminster).—International Conference on the Blind.

July 6th-11th (Blackpool).—Twenty ninth Congress of the Royal Sanitary Institute.

" 8th-10th (Oxford).—Ophthalmological Congress.

July 8th-13th (Edinburgh).—Congress of the Royal Institute of Public Health.

„ 21st-23rd (Chester).—British Pharmaceutical Conference.

„ 27th-31st (London).—Fifth Annual Session of the Clinical Congress of Surgeons of North America.

„ 28th-31st (Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.

Aug. 3rd-8th (London).—Sixth International Dental Congress.

„ 10th-15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.

Sept. 7th-12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.

„ 30th-Oct. 3rd (Brussels).—Fourteenth French Congress of Medicine.

September (Vienna).—Third International Congress for Diseases of Occupation.

Nov. 15th-21st (London).—Health Week. (Under the direction of the Health Week Committee appointed by the Royal Sanitary Institute.)

(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.

In 1915:—

May 31st-June 5th (London, South Kensington).—Sixth International Congress of Social Work and Service.

Sept. 8th (begins) (Manchester).—Meeting of the British Association.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Sir James Stirling: Note on a Functional Equation employed by Sir George Stokes.—Prof. J. C. McLennan and Mr. A. R. McLeod: On the Mercury Green Line $\lambda = 5461$ as Resolved by Glass and Quartz Lummer Plates and on its Zeeman Components (communicated by Sir J. Larmor).—Mr. H. Hartley: The Electrical Condition of a Gold Surface during the Absorption of Gases and their Catalytic Combustion (communicated by Prof. W. A. Bone).—Mr. J. H. Mackie: The Diffusion of Electrons through a Slit (communicated by Prof. J. S. Townsend).—Dr. A. Holt: The Rate of Solution of Hydrogen by Palladium (communicated by Mr. G. T. Beilby).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF SURGERY (Hon. Secretaries—J. Murray, Raymond Johnson): at 5.30 P.M.

Paper:

Mr. Herbert J. Paterson: Gastro-jejunostomy: the Principles which should Determine its Application and the Indications for its Use.

SECTION OF PSYCHIATRY (Hon. Secretaries—R. H. Cole, Bernard Hart): at 8.30 P.M.

(Joint Meeting with British Psychological Society.)

Mr. W. McDougall, F.R.S.: The Definition of the Sexual Instinct.
Dr. H. Devine: The Biological Significance of Delusions.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—W. Essex Wynter, T. H. Kellock): at 8.30 P.M.

Cases:

Mr. Henry Curtis: Case of Primary Squamous Epithelioma of the Exterior of the Left Nostril Illustrating the Radical Modern Operation.

And other Cases.

Short Paper:

Mr. V. Zachary Cope: Traumatic Sensory Aphasia.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Radium Therapy, introduced by Mr. H. Pinch. Followed by Sir Frederick Treves, Bart., G.C.V.O., Sir A. Pearce Gould, K.C.V.O., Mr. A. C. Morson, Dr. H. Williamson, Mr. T. H. Kellock, Mr. D. Harmer, Dr. Finzi, Dr. D. Turner, and Dr. L. Jones.

CHELSEA CLINICAL SOCIETY, Club Rooms of the Medical School, St. George's Hospital, S.W.

TUESDAY.—8.30 P.M., Annual Clinical Debate on Arteriosclerosis. Paper:—Prof. L. Hill: New [illegible] nent of Blood Pressure in Man. [illegible] hich Dr. McQueen, Dr. M. Flac [illegible] and others will take part.

HUNTERIAN SOCIETY, Library, St. Bartholomew's Hospital, E.C.

WEDNESDAY.—9 P.M., Papers:—Dr. W. H. Kelson: Nasal Suppuration, more Particularly as Associated with Diseases of the Eye.—Dr. R. D. Maxwell: Specimens of Two Fœtal Heads—(1) Hydrocephalic, (2) Defective Ossification—with Remarks on their Obstetric Significance.—Mr. A. S. B. Bankart: Colles's Fracture and its Treatment.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY.—9 P.M., Dr. C. O. Hawthorne: The Clinical Value of the Instrumental Estimation of Blood Pressure.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

THURSDAY.—5 P.M., Major E. T. F. Birrell, R.A.M.C.: Some Experiences of the Balkan War.

THURSDAY.—8.30 P.M., Harveian Lecture:—Mr. D'Arcy Power: English Medicine and Surgery under Edward III. (illustrated by lantern slides).

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Board Room of the Great Northern Central Hospital, Holloway-road, N.

THURSDAY.—9 P.M., Paper:—Dr. L. Barlow: Radium and Radiation as a Therapeutic Agent.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY, Johnston's Rooms, 6, Broadway, Wimbledon, S.W.

FRIDAY.—9 P.M., Address:—Mr. J. S. Joly: The Diagnosis and Treatment of Enlargements of the Prostate.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Goulstonian Lectures:—Dr. M. A. Cassidy: Rheumatoid Arthritis. (Lectures I. and II.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Hunterian Lecture:—Prof. C. M. Moullin: *Observations on the Biology and Classification of Tumours.*

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. W. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Sir George Savage: Syphilis and Insanity.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—*Dr. W. H. Stoddart: The Modern Treatment of* General Paralysis.

WEDNESDAY.—4 P.M., Mr. W. Turner: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. A. E. Giles: The Evolution of Hysterectomy.

THURSDAY.—4 P.M., Mr. C. W. Rowntree: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. J. McCann: The Treatment of Infection of the Female Genitalia.

FRIDAY.—4 P.M., Mr. R. E. Bickerton: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, *Dr. Bernstein: Pathological Demonstration.* 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Saunders: Gastro-intestinal Disorders of Infancy and Childhood.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Gastro-intestinal Disorders of Infancy and Childhood.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Saunders: Gastro-intestinal Disorders of Infancy and Childhood.

THURSDAY.—9 A.M., Dr Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. *X Rays.* Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Saunders: Gastro-intestinal Disorders of Infancy and Childhood.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Gastro-intestinal Disorders of Infancy and Childhood.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. *Mr. Pardoe: Operations.*

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). X Rays and Electrical Methods. 3 P.M., Special Demonstration of Selected Medical Cases (Dr. R. M. Leslie). Medical In-patient (Dr. Whiting). 4.15 P.M., Lantern-Demonstration:—Mr. Howell Evans: Strictures and Kinks of the Small Intestine.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R P. Brooks). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on Syphilology:—

TUESDAY.—4.15 P.M., Dr. O. Grunbaum: The Viscera.

WEDNESDAY AND FRIDAY.—4.15 P.M., Mr. A. B. Roxburgh and Mr. W. T. Lister: The Eye.

[illegible]

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4.30 P.M., Lecture:—Dr. S. Melville: The Technique of the X Ray Examination of the Lungs.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

FRIDAY.—5 P.M., Lecture-Demonstration:—Dr. Stott: The Use of Graphic Records in Heart Disease.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY AND FRIDAY.—3 30 P.M., Lectures.—Dr. H. Tooth: Clinical Cases.

QUEEN'S HOSPITAL FOR CHILDREN, Board Room of the Hospital, Hackney-road, N.E.

TUESDAY.—4 P.M., Lecture:—Dr. R. A. Chisolm: Anæmia in Childhood.

CANCER HOSPITAL, Museum of the Hospital, Brompton, S.W.

Post-Graduate Lectures on the Diagnosis and Treatment of Cancer:—

WEDNESDAY.—5 P.M., Mr. C. Rowntree: Cancer of the Breast.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—2 P.M., Dr. W. Griffith: Diseases of the Hair.
THURSDAY.—6 P.M., Dr. M. Dockrell: Treatment by Cataphoresis and Electro-inunction.

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture Room of the Institute, 37, Russell-square, W.C.

Course of Instruction for Tuberculosis Officers, School Medical Officers, Medical Practitioners, &c.:—

FRIDAY.—5 P.M., The Diagnosis and Treatment of Tuberculosis, &c.—Lecture IX.:—Dr. D. J. Williamson: Treatment—Tuberculosis Dispensaries.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

TUESDAY.—7.30 P.M., Discussion on Social Conditions in Relation to [illegible] Hilda Clark: The [illegible] Side; Dr. F. E. [illegible] Question.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

TUESDAY.—SALFORD ROYAL HOSPITAL—4.30 P.M., Mr. G. Wright. Demonstration of Surgical Cases in the Wards.
WEDNESDAY.—ROYAL INFIRMARY—4.30 P.M., Dr. W. E. Fothergill A New Modification of Colporrhaphy.
THURSDAY.—ANCOATS HOSPITAL—4.30 P.M., Dr. Leech: Enemata.
FRIDAY.—ROYAL EYE HOSPITAL—4.30 P.M., Dr. Hill Griffith Congenital Abnormalities.

ROT[illegible]

[illegible] Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1913 were given in THE LANCET of Dec. 27th, 1913.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1913 are now ready. Bound in cloth, gilt lettered, price 16*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*, by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following journals, magazines, &c., have been received:—Schmidt's Jahrbucher, Journal of Physiology, Ophthalmoscope, Journal of the Royal Sanitary Institute, Revista de la Sociedad Médica Argentina, Practitioner, Archives of Diagnosis, Archives of Internal Medicine, American Practitioner, Guy's Hospital Gazette, Biochemical Journal, St. Bartholomew's Hospital Journal, British Review, Medical Journal of South Africa, South African Medical Record, Proceedings of the Royal Society of Medicine, Magazine of the *London (Royal Free Hospital) School of Medicine for Women*, British Dental Journal, &c.

Hunterian Lecture

ON

CHANGES IN THE BLOOD IN THE CAUSATION OF SURGICAL SHOCK.

Delivered before the Royal College of Surgeons of England on Feb. 9th, 1914,

BY A. RENDLE SHORT, M.D., B.S., B.SC. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON AT THE BRISTOL ROYAL INFIRMARY; LECTURER IN PHYSIOLOGY IN THE UNIVERSITY OF BRISTOL; EXAMINER IN PHYSIOLOGY FOR THE FIRST F.R.C.S.

MR. PRESIDENT AND GENTLEMEN,—I desire to express my very sincere appreciation of the honour of being permitted to address you this afternoon. My subject is one of the meeting-places of physiology and surgery. These meeting-places are likely in the future to assume more and more importance. Anatomy has been the traditional road to surgery in the past, but it has almost paid the sum-total of its contributions towards the advancement of surgical science. Physiology, on the other hand, which has grown out of all knowledge in the past 20 years, still stands full of gifts, as the work of physiologists like Horsley, Crile, and Cushing has already shown. Primitive surgery had to face four apparently insurmountable barriers before it could fulfil its mission in the saving of human life and the relief of suffering. The first of these was hæmorrhage, and the victory had already been gained in Hunter's day. The second was pain. This barrier fell down when anæsthetics were introduced. The third was sepsis, a danger which Lord Lister showed us how to triumph over. The last great barrier to be conquered is shock, and we do not yet see how the assault is to be made. But three victories make us very confident of final success, and we believe that one day surgery will have lost its main terrors and will be able to bring benefit to patients who are now doomed to die unrelieved; for instance, cases of intracranial or intrathoracic disease, and what we now call inoperable carcinoma. We may not hope to prevent or treat surgical shock until we have an accurate conception of its nature and causation, and we shall proceed to pass in review some of the suggestions which have been made, and to see how they fare under the criticism of exact experiment. This review will be in a sense the mental autobiography of the writer, inasmuch as he has been attracted by each theory in turn, but on putting it to the test has had to give it up for another.

It will be useful first to quote from an esteemed writer the symptoms of shock as they appeared before attempts had been made to fit them into any of the modern theories. Sir W. Watson Cheyne[3] wrote in 1898: "The patient who is suffering from shock is usually found lying in a state of complete muscular relaxation, or if he makes any movements they are very irregular and feeble. The face is pale and drawn, the pupils dilated, there is sweating about the head, the reflexes are very slight, there is diminished sensibility, but not absolute unconsciousness. The patient can answer questions when spoken to, but if not disturbed will generally lie in a semi-conscious condition. The respirations are feeble, irregular, and sighing. The pulse is small, frequent, and dicrotic. At first the pulse-rate is generally slowed, and increased frequency of the heart beat is regarded by some as a sign of the commencement of reaction. The skin is cold; the temperature subnormal." With the possible exception of the statements concerning the pulse-frequency, this clinical picture will command universal assent. We shall have to refer to it repeatedly.

THE THEORY OF CRILE AND MUMMERY.

Some of us well remember the eager interest with which we read Mr. J. P. Lockhart Mummery's exposition of this theory in 1905. His work was in the main a confirmation of the laborious researches of Professor Crile in America. The essence of the theory is that the vaso-motor centre in the brain is first stimulated and then exhausted by painful, or as we should now say nociceptive, impulses coming to it from the afferent nerves. All the phenomena of shock are due to this primary exhaustion of the vaso-motor centre. The most characteristic index of shock is the fall of blood pressure. It will not be necessary here to set forth the arguments by which this view was defended. Surgery undoubtedly owes a great debt to Crile's researches. He has established for us the importance of the sphygmomanometer in measuring shock, the value of nerve-blocking in preventing it, and the general principles of its avoidance and treatment. Nevertheless, it is scarcely going too far to say that the theory is beyond doubt erroneous. It has been maintained by a number of competent observers, both on clinical and experimental grounds, (*a*) that the peripheral arteries may be contracted, not dilated, during shock; and (*b*) that the vaso-motor centre is not necessarily exhausted, even in extreme shock. If the failure of the vaso-motor centre was the main factor in the genesis of shock, an examination of the pulse and blood pressure would be a sure indication of the patient's condition. No doubt a bad pulse and a fall of tension are grave signs, but no surgeon, anæsthetist, or practitioner accustomed to judge of the prospects of a patient after a severe operation will dare to maintain that because the pulse is good and the blood pressure normal there can be no fear of death from shock. Only too commonly, in spite of an apparently efficient vaso-motor centre when the patient leaves the table, severe depression of all the vital functions comes on a few hours later and death follows. There may be shock, then, with a normal blood pressure.

Again, Mr. J. D. Malcolm[4,5,6] has repeatedly pointed out that the condition of a patient in shock does not correspond with the clinical picture of vaso-motor paralysis. Compare it, for instance, with belladonna poisoning, in which the small arterioles are undoubtedly released from nervous control, causing, as we know, a flushed skin. In shock, on the other hand, the skin is pale, the pulse is small, bleeding is scanty, and the anuria suggests that the renal vessels are contracted. The abdominal viscera are pale unless they have been long exposed. Seelig and Lyon point out that the retinal blood-vessels are contracted to one-half or one-third their normal calibre, and amaurosis may occur (it is possible, however, that the retinal vessels, like the cerebral, are not under the direct control of the vaso-motor system). Warmth does the patient more good than cold, whereas if the cutaneous vessels were dilated the reverse should be the case. Mr. Malcolm's observations have not attracted the credence they deserve, because it is so difficult to understand how there can be a fall in blood pressure with an efficient heart and contracted vessels.

Animal experimentation confirms the clinical

74, then pulse disappeared. Anæsthetic, $CHCl_3$ and open ether about equally; Clover at intervals. Specific gravity at beginning 1·048. Specific gravity at end 1·045. *Sequel*, died 3 days later.

2. Female, aged 63. Cancer of splenic flexure removed, 1½ hours. Very fat patient. Very little blood lost. Pulse good at end, but patient looked bad. Specific gravity at beginning 1·058. Specific gravity at end 1·060. *Sequel*, died suddenly 3 days later.

3. Female, aged 36. Post-partum shock. Lost 15 ounces of blood at confinement. Presentation normal; adherent placenta extracted under $CHCl_3$. Severe shock four hours later, pulse ?160, too feeble for blood pressure to be taken. Looked bad. Saline had been given per rectum. Six hours after delivery specific gravity 1·060. *Sequel*, recovered.

4. Male, aged 39. Intramedullary plugging for fractured femur; traction by Lambotte's extension apparatus. No hæmorrhage; one and a half hours. Severe operation, but very little shock; blood pressure at end 134. Specific gravity at end 1·061. *Sequel*, recovered.

5. Female, aged 50. Big breast cancer operation with supraclavicular glands; one hour. Several attacks of syncope, but not marked shock. At end, pulse 60, blood pressure 108. Specific gravity 1·060. *Sequel*, recovered.

6. Male, aged 30. Perforated typhoid ulcer, very bad. Near end, specific gravity 1·061. *Sequel*, died within 24 hours.

7. Female, aged 18. Extensive burns seven hours before, involving abdomen, buttocks, thighs, hands, and arms. Pulse good, but looked ill; vomiting; thirsty. Specific gravity, 1·072. Next day, specific gravity, 1·072. Twelve days later specific gravity, 1·059. *Sequel*, recovered.

8. Male, aged 40. Arthroplasty of hip; patient feeble, with ankylosed spine. Took one and a half hours. Pulse soft and feeble, disappeared at intervals. Blood pressure near end 85; temperature after operation 96·6°. Specific gravity at beginning 1·062. Specific gravity at end 1·063. *Sequel*, recovered. Blood pressure three days later 115.

9. Female, aged 36. Extensive cancer of stomach; vomiting incessantly for several days. Gastrojejunostomy. No signs of shock clinically. At beginning, specific gravity 1·055; at end, specific gravity 1·059. *Sequel*, recovered.

10. Female, aged 43. Wertheim's hysterectomy for cancer of cervix. Full anoci-association. Bladder wounded and sewn up. Bad shock at end (2 hours), pulse quick and feeble, blood pressure 70. At beginning, specific gravity 1·046; at end, specific gravity 1·047. *Sequel*, died 15 hours after.

11. Female, aged 62. Jumped from a window. Fractures of both femurs; scalp wound. Six hours after specific gravity 1·060. *Sequel*, recovered.

12. Female, aged 29. Severe burns from knees to umbilicus 10 hours before. Pulse quick and feeble, marked shock. Specific gravity 1·073. *Sequel*, recovered.

13. Girl, aged 2½. Burns of face and thighs, about 9 inches square. Pulse 90, no shock. Blood taken 4 and 8 hours after. Specific gravity 1·060. *Sequel*, recovered.

both died from it, yet the specific gravity of the blood showed a fall in one case and a wholly insignificant rise in the other. Nothing but a rise of 0·010 would be sufficient to indicate a loss of fluid likely to reduce the blood pressure. We may take it, therefore, that the oligæmia theory of Cobbett and Vale is definitely disproved as the ordinary cause of surgical shock. We notice, further, that the only operation case which showed a marked rise was a bowel anastomosis. Sherrington, and also Roy and Cobbett, made their original observations on the specific gravity of the blood on animals whose intestines were manipulated. Probably this handling leads to an effusion of fluid into the peritoneum.

By a singular mischance it was only possible to obtain the blood of two severe burn cases. These showed a most remarkable rise in the specific gravity in one patient amounting to 0·013, and lasting over 24 hours. This corresponds to a loss of fluid of about a quart from the circulation, and probably explains the thirst and the vomiting. Perhaps further investigation may show that in burn cases oligæmia *is* an important factor in the causation of shock. It is quite clear that the administration of as much fluid as possible is urgently indicated.

A third point of interest is with reference to the two cases of Wertheim's hysterectomy (Cases 1 and 10). It will be observed that the specific gravity before operation was very low—1·048 and 1·046, instead of 1·057. This was probably the result of prolonged loss of blood. Both cases died from shock. It has been found by Douglas that a fall in the specific gravity of the blood is common in cancerous cachexia. We may have here an easy means of detecting cases whose general condition is already too grave to permit of major surgery. The estimation of the specific gravity is simple, only takes three minutes, and can be done with a drop or two of blood. It remains to be determined just where the limits of safety lie. In the two fatal cases there was a fall of 0·010. The writer has performed a big operation with no ill effects on a man whose blood was reduced to 1·053.

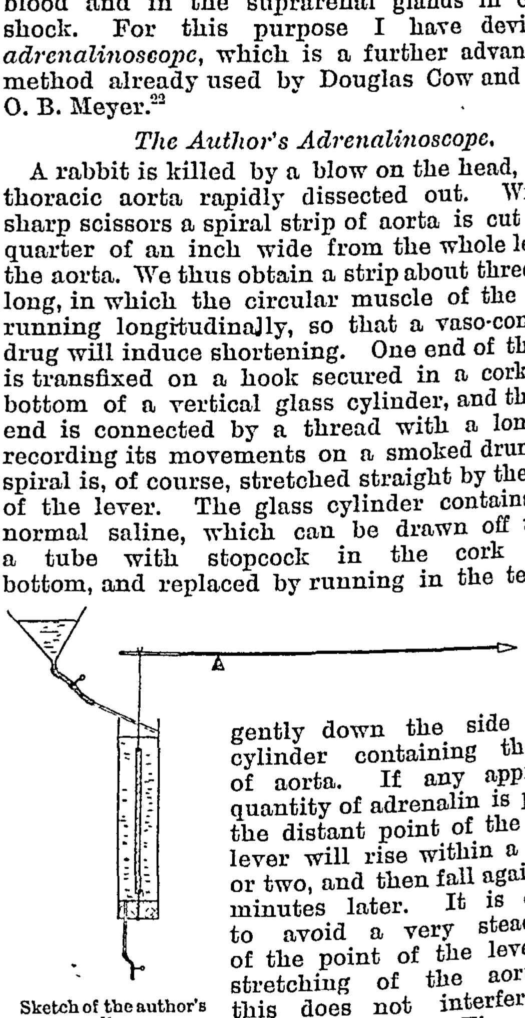
THE SUPRARENAL EXHAUSTION THEORY.

Perhaps no one has definitely formulated any such theory as yet, but it is certainly deserving of examination. Recent physiological research has shown that painful stimuli lead to a reflex outpouring of adrenalin from the suprarenal glands into the circulating blood (Elliott,[18] von Anrep,[19] Levy[21]). If this took place to a considerable extent there would be a preliminary rise of blood pressure, followed, perhaps, by suprarenal exhaustion and a profound fall of pressure in spite of a normal heart and vaso-motor centre. Bainbridge and Parkinson[20] found absence of the chromaffin substance in the medulla of the suprarenals in two patients who died from shock. Priestley found the same absence in 84 per cent. of cases dying with a low blood pressure. Here, at least, is a *primâ facie* case for the suprarenal exhaustion theory.

Examination of the chromaffin substance is not a very convincing means of settling the problem. It is quite probable that the chromaffin substance and the adrenalin content run parallel, and there are observations in support of this view, but it would be much more satisfactory to make direct estimations of the quantity of adrenalin in the blood and in the suprarenal glands in cases of shock. For this purpose I have devised an *adrenalinoscope*, which is a further advance on a method already used by Douglas Cow and also by O. B. Meyer.[22]

The Author's Adrenalinoscope.

A rabbit is killed by a blow on the head, and the thoracic aorta rapidly dissected out. With fine sharp scissors a spiral strip of aorta is cut about a quarter of an inch wide from the whole length of the aorta. We thus obtain a strip about three inches long, in which the circular muscle of the aorta is running longitudinally, so that a vaso-constrictor drug will induce shortening. One end of the spiral is transfixed on a hook secured in a cork at the bottom of a vertical glass cylinder, and the upper end is connected by a thread with a long lever recording its movements on a smoked drum. The spiral is, of course, stretched straight by the weight of the lever. The glass cylinder contains warm normal saline, which can be drawn off through a tube with stopcock in the cork at the bottom, and replaced by running in the test fluid gently down the side of the cylinder containing the strip of aorta. If any appreciable quantity of adrenalin is present, the distant point of the writing lever will rise within a minute or two, and then fall again a few minutes later. It is difficult to avoid a very steady fall of the point of the lever from stretching of the aorta, but this does not interfere with the reaction. (See Figure.)



Sketch of the author's adrenalinoscope.

This adrenalinoscope is extraordinarily delicate, and will show an appreciable contraction with as little as 1 in 500 million of Parke, Davis, and Co.'s adrenalin (i.e., 1 in 500,000 of their solution, which is 1 in 1000). I have used this method, first, to find whether there is any evidence that the blood is flooded with adrenalin during a surgical operation; and second, to estimate the relative quantity of adrenalin left in the suprarenal glands after death from shock. In two cases, which were the same as those numbered 8 and 9 amongst the specific gravity estimations, a hypodermic syringeful of oxalated blood was withdrawn from a vein towards the end of the operation, and diluted with sufficient saline to fill the glass cylinder containing the spiral strip. In neither case was any adrenalin contraction recorded.

It may be objected that there would not be sufficient adrenalin in the circulating blood of the patient to react even to so delicate an adrenalinoscope as one detecting 1 in 500 million, but calculating from the supposed quantity in the human suprarenals, 5 milligrammes according to Battelli,[23] it is difficult to believe that the glands could be exhausted in an hour or two and yet the amount in the blood escaped recognition.

More convincing, perhaps, are observations on the suprarenal glands of patients dying from shock. These were removed as soon as possible after death (from 6 to 24 hours), packed and transported in ice, cut open in 15 c.c. of normal saline, and the medullas thoroughly scraped out. Various dilutions in normal saline were then tested in the adrenalinoscope to determine the highest dilution giving a definite rise of the lever. Thus in Case A, strong solution of the suprarenal extract in saline, great rise of lever; 2 drops of suprarenal extract in 50 c.c. saline, 12 mm. rise; 2 drops of suprarenal extract in 500 c.c. saline, 1 mm. rise; and weaker solutions of the suprarenal extract, no rise. The results in four cases of death from shock and three control cases are set out in Table III.:—

TABLE III.—*Examination of Suprarenal Glands for Adrenalin after Death from Shock and in Control Cases. Medulla of both Suprarenals Extracted in 15 c.c. of Normal Saline.*

		Highest dilution causing contraction
	I.—*Shock Cases.*	
A	Male, aged 46. Nephrectomy for enlarged kidney, nature doubtful. At necropsy second kidney found not functioning. Died 4 hours after operation	1 in 4250
B.	Woman, aged 43. Wertheim's hysterectomy for cancer (= Case 10 in Table II.). Died 15 hours after operation	1 in 850
C.	Male, aged 53. Fell from ladder Fractured pelvis, fractured humerus, retroperitoneal hæmatoma. Died 2½ hours after fall	1 in 850
D.	Female, aged 65. Knocked down by taxicab and died 4½ hours later. Necropsy showed fractured pelvis and sternum	1 in 6000
	II.—*Control Cases.*	
E.	Male, aged 40. Symptoms of chronic heart failure. Syphilitic aortitis and myocardial degeneration	1 in 850
F.	Female, aged 46. Acute uræmia. Contracted granular kidney. Ill about a week. Blood pressure 240	1 in 4250
G.	Male, aged 33. Acute miliary tuberculosis	1 in 4250

It is a curious coincidence that all but one of the cases should chance to fall into two groups of dilutions.

It is quite clear from the analyses that adrenalin exhaustion is not the significant factor in the causation of shock. The suprarenals are by no means exhausted. In two cases the adrenalin was as high as, or higher than, in the controls. According to Cevidalli and Leoncini,[24] the adrenalin content. measured by a colorimetric test, is low after a chronic illness. Anæsthetics are said not to affect it.

WHAT, THEN, IS THE NATURE OF SURGICAL SHOCK?

We have failed to discover any evidence that changes in the blood are the essential factor in the production of surgical shock, and are left face to face again with the crucial problem, how to find an explanation for a falling blood pressure with a normal heart and vaso-motor centre and contracted peripheral arteries. Since the examination of the blood has not helped us, we must return to the *central nervous system*.

There is a condition well known to experimental physiologists called *spinal shock*. In monkeys, and to a much less extent in cats and dogs, a high transection of the spinal cord is followed by grave interference with the functions of the cord distal to the section. For a period varying from hours to days no reflexes can be obtained, muscular tone is abolished, and the peripheral blood-vessels dilate. In human surgery we see the like condition in spinal concussion, in which, after a blow on the back, sensation, voluntary power of movement and reflexes may be abolished, but after a day or two are all restored to normal.

Professor Sherrington[25] has made some important investigations into the nature of spinal shock. In the first place, he shows that it only affects those segments of the cord distal to the lesion; thus, after an upper dorsal transection the cervical segments are not in shock. Secondly, he shows that after recovery has taken place a second transection—for instance, in the mid-dorsal region—will not reproduce the signs of spinal shock, proving that it was due to the withdrawal of influences descending from the brain or brain stem. Again, cutting across the mesencephalon, above the pons, does not induce spinal shock. Therefore the impulses preventing it must have come down from the region of the fourth ventricle. We also know that from this same region, and in particular from the central nuclei of the vestibular nerve, descend the impulses which give rise to excess of muscular tone. A transection of the mid-brain causes decerebrate rigidity of the limbs; a second transection below the medulla abolishes the excess of tone. On this subject the writings of Sherrington and of Thiele[26] may be consulted.

F. H. Pike,[27] of Columbia University, has lately published a very important research on spinal shock with particular reference to the blood pressure. He shows that there is a certain residual blood pressure, about 33 mm. of mercury, even after removal of the brain, provided that the cord is left intact, and that sensory stimuli will raise this pressure reflexly. When the cord is totally removed there is a very great fall of pressure. Apart from removal of the cord, curare produces a considerable reduction of blood pressure, both in normal and in spinal animals. This curare effect is not due to any action on the vessels, but to the abolition of tone of the voluntary muscles. This is in accord with the results of other workers.

Do we not here find a clue to our problem? We turn back to the very first sentence of Sir Watson Cheyne's classical description of shock, and read, "The patient who is suffering from shock is usually found lying in a state of complete muscular relaxation." And, later, "the reflexes are very slight." Loss of tone in the voluntary muscles, in the abdominal wall especially, allows great dilatation of the veins, and here, as Crile observed in his experimental animals, the blood accumulates. Therefore the blood pressure falls and the cardiac output is reduced, in spite of undiminished power of the heart muscle and contracted arteries.

We must draw attention to the very significant fact that although the intramuscular and abdominal veins are dilated in shock, this cannot be due to some universal veno-dilator effect, because, as anyone who has had to perform intravenous transfusion on these cases will bear witness, the subcutaneous veins are smaller than normal. It may be objected that muscular tone is reduced in various nervous diseases and under anæsthetics without a marked fall of blood pressure, but it has to be remembered that in the nervous affections the onset is very gradual and can be compensated, and with anæsthetics there is stimulation of the heart and vaso-motor centre to counteract the loss of tone. Under ether, at any rate, the muscles may be very vigorous, as rigidity of the abdominal wall frequently reminds us. Chloroform, of course, does reduce the blood pressure after a time.

Without venturing to formulate a cut-and-dried theory, then, one may suggest that the nociceptive impulses which bring about surgical shock do so by inhibiting or paralysing the important nuclei in the region of the fourth ventricle and perhaps in the cerebellum, which, as Sherrington and others have shown, are continually sending impulses down the spinal cord, maintaining its functional activity and increasing muscular tone. When such inhibition or paralysis takes place the functions of the cord are greatly reduced, tone is abolished, and therefore, as a secondary result, the blood pressure may fall. The respiratory centre, and perhaps even the vaso-motor centre, share in this inhibition or paralysis; this is a very different conception from that which takes exhaustion of the vaso-motor centre to be the prime cause of all the symptoms. Death is due to accumulation of blood in the great veins, so that the *vis a tergo* is no longer able to provide a proper filling for the heart, especially as the feeble respiratory movements fail to exert their important pumping action.

A very striking example of this sequence is met with in what is called "the knock-out blow" in pugilism, or rather, one of such blows. A vigorous drive on the point of the lower jaw in a line from the chin to the condyles is transmitted directly to the labyrinth of the internal ear, and by way of the vestibular nerve impulses reach the nuclei of which we have been speaking. As a result a powerful athlete is immediately reduced to a mass of quivering, unstrung flesh, and may die outright. In a word, he is in a state of shock.

Perhaps it may be found possible to localise with accuracy the nuclei which are principally affected in surgical shock by histological examination for chromatolysis. Dolley and Crile have published very remarkable observations on changes in the nerve-cells in shocked or hunted animals, showing dissipation of the Nissl granules. These changes were best marked, not in the vaso-motor centre as Crile's theory would demand, but in the Purkinje cells of the cerebellum. Tyrrell Gray and Parsons found changes in the cuneate and gracile nuclei of the medulla.

I have so far had the opportunity of examining the brain of only one case by this laborious method, and therefore must express conclusions with all reserve. The patient was a healthy man who died 2½ hours after a fall from a ladder which caused a fractured pelvis, fractured humerus, and retroperitoneal hæmatoma (Table III., Case C). The brain-stem and cerebellum were removed, hardened in formalin, sectioned with the freezing microtome, and stained by Nissl's method. The examination of a number of sections showed the following changes. Purkinje cells of cerebellum: All full of Nissl granules. No abnormal cells found in some hundreds examined. Cells of dentate nucleus of cerebellum: Practically all normal. Cells of various motor nuclei in medulla: All normal. Cells of inferior olive: The majority normal. A few showed reduction of Nissl granules. Cells of Deiters' nucleus (lateral vestibular): Some normal cells; majority showed considerable reduction of the granules, and many cells had practically none left. Cells of gracile and cuneate nuclei: Very remarkable absence of Nissl granules. Scarcely a granule to be found in the whole nucleus. We know that reduction of the Nissl granules is usually an evidence of exhaustion of nerve-cells, but it must distinctly be understood that we have no evidence that if a nerve cell is paralysed it must necessarily show histological changes, and absence of chromatolysis would not therefore prove that certain nuclei were able to function properly.

THE DIAGNOSIS, TREATMENT, AND PREVENTION OF SHOCK.

It must regretfully be admited that such a conception of shock makes diagnosis and treatment much more difficult. And first, *diagnosis* is difficult, because we may no longer place implicit reliance upon the blood pressure. No doubt a fall of pressure is our best sign of shock, but it ceases to be infallible. For instance, crushing the testis may induce a reflex depression through the vasomotor centre, which is perfectly recoverable without any other signs of shock. Again, and surely we have all learned only too well the truth of this, a patient may be far worse than the pulse and pressure would lead one to think. A diagnosis of shock nowadays must take into account the whole clinical picture described by Sir Watson Cheyne, as well as the readings of the sphygmomanometer.

In the *treatment* of shock, the failure of the simpler theories leaves us sadly bereft of our weapons for meeting it. It was so easy to give pituitary extract for paralysed vaso-motors, carbon dioxide for acapnia, intravenous or subcutaneous saline for oligæmia, and adrenalin injections for exhaustion of the suprarenals, and so hard to understand why they might one and all fail. But what can one do for paralysis of the nerve-cells of all the vital centres? Evidently it is not enough merely to raise the blood pressure, although that may help a little by driving more blood to the brain, and so give the damaged nerve-cells the most favourable conditions for recovery. Saline transfusion or infusion has its value in maintaining the output of the heart. Recently the use of sodium bicarbonate instead of chloride has been advocated by several American writers on experimental grounds, though they find it hard to give a satisfactory explanation of its action.

It is doubtful if pituitary extract or adrenalin do any good, and Crile's teaching as to the futility of strychnine and alcohol is probably correct. Happily it is possible, to some extent, to exert pressure on the dilated veins, and so replace the deficient muscular tone by means of elastic bandages for the limbs and abdomen, taking care not to impede the action of the diaphragm. Intraperitoneal saline fluid in large quantity would help in the same way. In cases of shock from burns the indications for introducing plenty of saline are clear.

It is to the *prevention* of shock that we must look with hope and some degree of confidence for the future. No doubt Professor Crile's anoci-association methods are on the right lines, but to use his native country's expression, he has not quite "got there" yet. For instance, Case 10 in Table II. died from severe and typical shock in spite of a long time spent in thoroughly injecting the abdominal wall with novocain and the peritoneal surfaces with quinine-urea-HCl before cutting. Moreover, quinine-urea-HCl is destructive to the tissues, and we urgently require a drug which will be long-lasting in its effect without causing necrosis. On the other hand, in some of the writer's own abdominal cases it has worked like a charm, abolishing both shock and after-discomfort. The method is novel and can probably be improved in its details, and in blocking the up-paths of painful stimuli, as far as we can now see, lies the hope of the future. That problem once solved, we should be able to operate on desperate cases without that fear of death on the table or within a day or two which at present forms the barrier against the emancipation of surgery to do its beneficent work unhindered.

The present lecture is as a scout sent forth to survey the barrier, and a scout's difficult ambition is to tell a tale which the future will prove true.

My very best thanks are due to my surgical colleagues at the Bristol Royal Infirmary for allowing me to make use of their cases, also to Professor A. F. Stanley Kent, Dr. J. R. Kay-Mouat, Mr. G. Scott Williamson, and Mr. Scott White for kind help. The expenses of the research were assisted by the University of Bristol Colston Research Fund.

CHILDREN'S HOME AT EXETER.—On Feb. 23rd the new home which the Exeter board of guardians have erected for children who were formerly resident in the workhouse was formally opened. The building is situated close to the workhouse at Heavitree, but quite separate from that institution. The cost is about £6500, and it will provide accommodation for 30 girls and 41 boys, with rooms for four attendants.

THE AGGLUTINATION OF M. MELITENSIS BY NORMAL COWS' MILK.[1]

BY P. W. BASSETT-SMITH, C.B., M.R.C.S. ENG., M.R.C.P. LOND.,
FLEET SURGEON, R.N.; LECTURER ON TROPICAL MEDICINE, ROYAL NAVAL COLLEGE, GREENWICH.

THE fact that the milk from cows in London is in some cases able to cause agglutination of the M. melitensis has lately been brought forward by Kennedy. He found a positive reaction with the milk of 3 out of 22 cows, and 5 times from mixed milks. The reaction was also obtained when using whey, but was diminished or altogether lost by filtering the milk through a Berkefeld or Doulton candle.

Anomalous reactions have frequently been described when examining goats' milk. In Malta Martel, Tannon, and Cretien state that as a means of diagnosis it is unreliable. In Algiers and Tunis in the laboratories of Sergent and Nicolle the importance of these lacto-reactions is highly rated, and Zammit carries out a very large number daily at Malta. Cows in the endemic area have been frequently noted by means of lacto-reactions as being infected, but I think no one depends upon it wholly for diagnosis.

It appears to be of the utmost importance to recognise *that the reaction is a specific one,* and that by its means an enormous amount of public health work for prevention of the spread of undulant fever is possible. It therefore renders it necessary to find out what error of technique has been committed to give rise to these misleading results. For two months I have been testing milks with this object without much success, but some of the reactions are so unexpected that I have ventured to bring them forward.

I first tested 16 samples of milk from separate cows with five different strains of M. melitensis at 1 in 2 dilution both microscopically and by sedimentation. Some strains were found to agglutinate much more easily than others. The type strain originally obtained from Wright at Netley acted best, the emulsion being made from a culture not more than 48 hours old. This was always controlled by specimens without serum, with normal serum, and with immune serum. A further series of samples from 21 other cows was obtained from two farms near. Besides these, 32 samples of mixed milks obtained from different dairies have been tested. A total of 69 samples.

I found that boiling the milk cut out all the reactions; that heating it to 60° C. for half an hour cut out some, but not all. That with the unheated milk of 37 individual cows—tested with equal parts of emulsion made with normal saline solution—3 reacted in ½ hour, 6 in 1 hour, and 6 by sedimentation; these were reduced to 2, 4, and 5 by heating the milk. (Table I.) In dilution of 1 in 20 of milk direct from the 21 cows I did not get any positive reactions either microscopically in 1 hour or by sedimentation with heated or unheated samples.

Of 32 samples of mixed unheated milks tested with equal parts of emulsion made with saline solution, 5 gave positive reactions in ½ hour microscopically and 11 by sedimentation. In dilution of

1 in 20 there were 9 positives in one hour and 11 by sedimentation. (Table II.)

I noticed that frequently with the mixed milks the reaction was more strongly marked in those that were diluted to 1 in 20 than in the low dilutions. I thought that it might be the diluting fluid at fault. Similar specimens were therefore put up with saline and distilled water, and examined microscopically and macroscopically with heated and unheated milks at 1 in 2 and 1 in 20 dilutions. 32 mixed samples were thus tested and the reduction of the positive reactions with the distilled water was very marked—12 to 4, both emulsions agglutinating well the immune serum control. With the 1 in 20 dilution of milk the positives were reduced from 11 to a doubtful 3. The highest reaction obtained was 1 in 100 with mixed milk, which did not rise higher than 1 in 20 with water dilution.

Heating cut out reactions of Nos. 23 and 24.

Nos. 7 and 23 agglutinated with saline solution up to 1 in 100 and up to 1 in 20 with HO_2

When the milk is kept the reactions may quickly change, as shown in Table III. A sample of unheated milk taken direct from a cow gave complete negative reactions to all the tests, but 38 hours after the dilutions with saline were all positive up to 1 in 20, but still remained negative with the water dilutions. Heated samples gave complete positive reactions after that time.

Showing change in reaction for time.

Five samples from individual cows which had given positive reactions in low dilutions were plated out for isolation of M. melitensis but without success. I was unable to obtain a sample of serum for testing, but all the cows were stated to be in perfect health.

In Malta the milk is tested direct in a dilution of 1 in 20, using saline solution, and observing by the sedimentation method only. In the last return 50 per cent. of the goats so tested gave a positive reaction, which is possibly too high, but the result is always controlled by a serum reaction before the animal is considered to be infected. In Algiers and Tunis a dilution of 1 in 30 is used, the specimen being examined both microscopically and by sedimentation methods for six hours.

Result.—Using a 48 hours' culture for the emulsion and a dilution of 1 in 20 in this series, none of the milk from 21 cows gave a positive reaction when examined quite fresh, but with mixed samples of milk a high proportion reacted positively at this dilution, most of which were cut out by using heated milk and diluting with distilled water instead of saline solution. In any case it is very necessary to centrifuge the milk very thoroughly and to examine it at once, using an emulsion made from the M. melitensis not more than 48 hours old, and even then a few errors will occur by false clumps in the sedimentation tubes carrying down micrococci with them.

There is no doubt that cows' milk in some cases has a natural tendency to agglutinate the M. melitensis, but if care is taken most of these non-specific reactions may be avoided. The reaction always requires to be controlled by other methods of diagnosis before an animal can be considered to be infected.

A CASE OF TRANSGASTRIC EXCISION OF A GASTRO-JEJUNAL ULCER.

By SIR BERKELEY G. A. MOYNIHAN, F.R.C.S. ENG.,
PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF LEEDS, AND SURGEON TO THE LEEDS GENERAL INFIRMARY;
AND
E. TISSINGTON TATLOW, B.A., B.CH., M.D. (T.C.DUB.)

THE operative treatment of a peptic jejunal or gastro-jejunal ulcer following a gastro-enterostomy is beset with many technical difficulties. This is notably true in cases where the original anastomosis has been of the posterior no-loop variety, and where in consequence the ulcer is somewhat inaccessible.

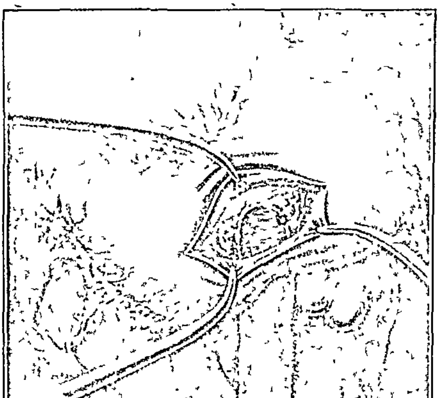
The usual procedure in operating for this type of ulcer is to resect the whole of the jejunal length engaged in the anastomosis, and also the adjacent portion of the stomach; and after this to make a new junction between the stomach and the jejunum. It is obvious that in a case where a posterior no-loop operation has been performed this resection of the entire anastomosis is exceedingly difficult, often indeed impossible; and even in the cases where it *is* possible a modified anterior Roux operation in "Y" has usually to be performed after the resection, the making of a second posterior anastomosis being an impossibility.

The method of transgastric resection for such cases of jejunal ulcer was suggested by Moynihan[1] in 1912, but the operation was not performed by him previously to this operation, the notes of which are given below, nor are we aware of any other surgeon having recorded a similar case.

The patient, a male aged 47, had a history of abdominal trouble extending over seven years. At the commencement his only symptom was epigastric pain on kneeling, on leaning forward, in fact, after any movement which caused contraction of his recti abdominis. Gradually this pain became more severe, occurring at almost regular intervals, independently of movement, and accompanied by flatulence and hyperacidity. The pain was of the variety known as "hunger pain," commencing from two to three hours after meals, and being relieved by lying down or taking food. There was never any vomiting. The site of the pain was above and to the right of the umbilicus. At first this pain was only felt at intervals; gradually, however, the intervals became shorter and the periods of pain longer. After three and a half years of this the patient had a sudden attack of severe abdominal pain in the right hypochondrium, which was diagnosed as a subacute perforation; from this attack he recovered without operation. In January, 1912, a posterior gastro-enterostomy was performed by another surgeon. The patient recovered from this operation, and his symptoms subsided only to return about eight months later. The pain after this was lower in the abdomen and more to the left than previously, and was really the only symptom he had; but this pain was severe in character, and for the last few weeks before admission to the nursing home almost constant in duration.

Dr. L. A. Rowden's X ray report was as follows:—"The bismuth feed passes freely through the œsophagus. The stomach is not dilated. The outline is regular except for an indentation about the middle of the greater curvature. Peristalsis is seen, *but it is not excessive. The gastro-enterostomy opening is patent; as far as I can judge about two-*thirds of the food passes through it and about one-third through the pylorus. The stomach is empty two hours after the meal. No food lodges in the duodenum nor is there any duodenal kinking. The small intestine is empty in 12 hours. No stasis. No ileal kink. In 24 hours almost all the bismuth has been passed per rectum. I have seen no abnormality in the large intestine. There is no X ray evidence of calculus in either kidney, in the ureters, or in the bladder."

On Jan. 7th, 1914, the abdomen was reopened by Sir Berkeley Moynihan and the notes which follow are by Dr. Tatlow, who assisted at the operation. The scar of the previous operation was excised and for the deeper portions of the incision Crile's anæsthesia was adopted. The transverse colon, which presented in the wound, was markedly hypertrophied and distended and also kinked in a very curious fashion—its middle portion being adherent to the under surface of the left lobe of the liver and to the diaphragm. Before the stomach could be examined it was necessary to separate the adhesions fixing the colon in this unusual position. This separation was exceedingly difficult owing to the inaccessibility of the parts. The stomach itself was normal in outline, but there was a scar of an old ulcer on the anterior surface of the first stage of the duodenum. The anastomosis which had been performed was a posterior, vertical, no-loop gastro enterostomy. The stoma was of adequate size and in the correct position. On feeling the stoma with the finger a



Transgastric excision of a gastro-jejunal ulcer following gastro-enterostomy.

---

[1] Duodenal Ulcer, 1912, p. 204.

hard nodule the size of a shilling, with a dimple in its centre, could be detected. This nodule, which was thought to be a gastro-jejunal ulcer, could be clearly palpated through the anterior wall of the stomach. In view of the technical perfectness of the original operation and the consequent difficulty of a local resection (posterior) it was decided that a transgastric excision of the ulcer would be a safer operation than an excision of the entire anastomosis. Accordingly, while the assistant passed two fingers, one on either side of the jejunal loop so as to grip the ulcer, a longitudinal incision was made through the anterior wall of the stomach parallel to the curvatures and midway between them. On opening the stomach the posterior wall was everted through the incision, thus bringing the gastro-jejunal ulcer into view. The ulcer was almost entirely gastric, being just on the edge of the stoma. On opening the stomach a piece of silk (? or linen thread) was found hanging loose from the region of the ulcer. Excision was performed with scissors, and the opening made in the posterior wall of the stomach closed with through-and-through sutures passed from the mucosa. The anterior incision was then closed, leaving only room for a No. 14 rubber catheter, which was passed into the stomach and along the efferent jejunal loop. After the closure of the anterior incision a few interrupted Lembert sutures were passed posteriorly in the region of the original anastomosis to make things quite snug; the abdomen was then closed, leaving the catheter *in situ*. The patient was given four ounces of peptonised milk through the gastrostomy tube before leaving the table.

The patient made an uneventful recovery from this operation. On the twenty-first day the gastrostostomy (or gastro-jejunostomy) tube was removed and feeding by the mouth commenced. Ten days later the patient left the nursing home in excellent health and enjoying a light white meat diet.

Leeds.

THE TECHNIQUE OF THE WASSERMANN REACTION,

WITH SPECIAL REFERENCE TO THE USE OF ANTIGENS CONTAINING CHOLESTERIN.

BY CARL H. BROWNING, M.D. GLASG.,
DIRECTOR OF THE LABORATORY OF CLINICAL PATHOLOGY OF THE WESTERN INFIRMARY AND UNIVERSITY, GLASGOW.

THE Wassermann reaction has now come to occupy a recognised place as one of the most accurate diagnostic methods available in medicine. But this estimate of its value can be substantiated only when the test is carried out under adequately controlled conditions. Hence, any contribution to our knowledge of the reaction which will lead to an increase in delicacy and precision must be welcomed. A great variety of procedures have been introduced, each making more or less serious claim to be an improvement on or a simplification of the original reaction. Certain methods are admitted to yield too high a percentage of positives, and these to any logical mind must be completely disregarded so far as their employment for diagnostic purposes is concerned; it is obvious that any form of the test which is liable to return positive reactions in cases which are not syphilitic is useless for diagnosis, however valuable such a method may be as an indication for the continuance of treatment in known cases of syphilis.

It is unnecessary to enter here into a discussion of the nature of the reaction, since nothing is accurately known concerning this question beyond the fundamental fact that a mixture of syphilitic serum and an emulsion of certain so-called "lipoid" constituents of animal tissues (the syphilitic "antigen") has the property of abolishing the complementing action of serum (from the guinea-pig), whereas a mixture of normal serum with the same "lipoid" emulsion possesses this action on complement to a much smaller degree. It is to be noted that, so far as we are aware at present, there is *no qualitative difference* between normal and syphilitic sera in their behaviour in the Wassermann test, but merely a quantitative difference. Such being the case, it is obvious that the limit of reacting power which differentiates a positive serum from a negative one must be arbitrary, and requires to be fixed by experiment for any given combination of "antigen" and serum. The standard is determined by examining a large number of sera from conditions which are known to yield positive reactions in most cases—e.g., general paralysis or secondary syphilis, and also sera from known non-syphilitics. When the results have been obtained in an extensive series of tests of this kind it is then possible to fix the limit of reacting power which a serum must reach in order to be counted positive, or below which a serum must fall in order to be recorded as negative. The validity of this method of fixing the criterion of the reaction is determined by the fact that sera from a known syphilitic condition such as general paralysis or cases in the secondary stage present all degrees of reacting power, and there is no necessary correlation between the clinical severity of the syphilitic infection in two cases and the grade of positiveness of their sera. Thus, Muir aptly says: "There will accordingly always be a certain proportion of cases which are almost positive, as well as those which are clearly so," and it is only by carrying out the reaction under strictly quantitative conditions, where the amount of complement (estimated in hæmolytic doses) which is absorbed by a given mixture of serum and of "antigen" is measured and controlled by comparison with the amounts fixed by each reagent separately, that conclusive results can be obtained.

Any method of carrying out the Wassermann test which is to be satisfactory must detect the greatest possible proportion of syphilitics, and at the same time must not include as positive any non-syphilitic sera. It is probable that a variety of procedures have been devised by different conscientious workers so as to fulfil those requirements. A method of carrying out the test described originally by Browning, Cruickshank, and McKenzie[1] has been extensively employed by nearly a dozen different workers in connexion with the Pathological Laboratory of the University and Western Infirmary, Glasgow, during the past three years, and the investigation of upwards of 3000 cases has yielded important clinical results, a *résumé* of which was recently published by me.[2]

One feature of our method of carrying out the test depends on the use of an "antigen" containing ox-liver "lecithin" along with cholesterin. The remarkable effect of cholesterin in increasing the action of "lecithin" as syphilitic "antigen" was first of all drawn attention to by Browning, Cruickshank, and McKenzie, and has since been confirmed by Sachs,[3] McIntosh and Fildes,[4] Walker and Swift,[5] and others, and "antigens" containing cholesterin have now come into very general use. Before our procedure was employed here for routine diagnostic purposes Gilmour[6] established the reliability of the method by the examination of 150 sera, about half of which were from cases of general paralysis, employing the lecithin-cholesterin "antigen" simultaneously in parallel series with a crude alcoholic tissue extract. The reliability and delicacy of the method has also been confirmed by Miss Muirhead,[7] and recently Watson (*v.* Browning[4]) has again confirmed the accuracy of the method by a very critical and extensive examination. In view of the great mass of evidence in support of the value of "antigens" containing cholesterin it is surprising that Thiele and Embleton[8] have recently come to the conclusion that "the use of cholesterin .... in antigens for the Wassermann reaction is not only unnecessary but introduces a very serious source of error." Such a statement cannot at the present time be allowed to pass unchallenged, since if it were correct it would discredit the value of all the work done by such methods.

Thiele and Embleton have entered in some detail into the conditions under which a suitable antigen is obtained from tissues, and they conclude that "the antigenic value of an antigen depends on the degree of autolytic degradation that it has undergone before extraction." This may be taken as correct; Citron,[9] writing in 1909, considered that the extract of syphilitic liver was enhanced in efficiency if autolysis had occurred beforehand, and Browning and McKenzie[10] record their observation regarding a congenital syphilitic liver containing spirochætes, but without any fatty or autolytic change. They found that this syphilitic fœtal liver yielded an extract in no way superior in its action as syphilitic "antigen" to that from a normal guinea-pig's liver. In the case of normal tissues Cruickshank (*v.* Browning and McKenzie[10]) found that, in general, organs which had undergone aseptic autolysis yielded extracts which had a very powerful antigenic action, but the extracts of such autolysed tissues by themselves exert an active hæmolytic and anticomplementary effect, so that their use may be attended by numerous disadvantages (*v.* Browning and McKenzie[10]) which render them of little value practically.

The action of "purified" phosphatids as syphilitic antigens has been recently investigated by Thiele and Embleton, who state that "all the phosphatids can act as good antigens provided they are extracted from suitably autolysed tissues." In this connexion it must be remembered that the preparation of a *pure* phosphatid is a matter of remarkable difficulty, as especially Cruickshank[12] and MacLean[13] have shown, and there is some reason for doubting whether a pure phosphatid has ever been prepared. Investigating the action of "lecithins" (so-called N_1P_1 phosphatids) prepared under precisely comparable conditions from various tissues in the normal fresh state, Browning, Cruickshank, and Gilmour,[14] however, have shown that the a [illegible] lepends to a very great [illegible] tissue from which the [illegible] the product from egg [illegible] n, that from heart is extremely powerful, while liver yields a substance of intermediate activity.

With regard to the effect of cholesterin in an antigen, it must be remembered that practically all tissues contain this substance, and in the liver in cases of congenital syphilis Pighini[11] has found that cholesterin is often present in excess. Thiele and Embleton, however, do not appear to object to the use of extracts of congenital syphilitic liver as antigen.

Cholesterin it[illegible] action as Pigh[illegible] Browning and [illegible] a watery colloidal solution of cholesterin to human serum the mixture sometimes exhibited a greater inhibitory action towards complement than did the cholesterin solution by itself; this is the phenomenon to which, apparently, Thiele and Embleton have now applied the term "anticomplementary adjuvant phenomenon," but occasionally serum has the opposite effect and diminishes the anticomplement action of the cholesterin. Browning and Cruickshank recognised that the action on complement of a mixture of serum with cholesterin alone was irregular and possessed no diagnostic significance as regards syphilis.

The action of cholesterin along with "lecithin" is quite different, however. When an alcoholic mixture of "lecithin" and cholesterin is emulsified with physiological salt solution in such a fashion as to give a turbid suspension (*v.* Browning and McKenzie[10]), it is found that the anticomplement effect of the cholesterin is abolished; such a suspension has, in fact, practically no more inhibitory action on complement than a similar emulsion of the same "lecithin" by itself. The striking fact, however, emerges that the lecithin-cholesterin emulsion along with syphilitic serum absorbs more complement than does the mixture of serum and lecithin in the absence of cholesterin. Further, this effect of cholesterin in increasing the amount of complement absorbed by serum occurs only when the serum is syphilitic. Obviously, we are not here dealing with a mere summation of effects; hence this phenomenon serves as a specific indication that the serum under examination is syphilitic. Especially in the case of weakly positive sera, this reaction constitutes a valuable addition to the ordinary criterion for detecting a positive reaction (i.e., measuring the number of doses of complement absorbed by the mixture of serum and "antigen" as compared with the sum of the amounts inhibited by each constituent separately). An example, one of many hundred similar experiments, is appended (see p. 742) in confirmation of previous results.

In view of these facts the statement of Thiele and Embleton that "cholesterin merely magnifies any anticomplementary effect whether already present or induced by the Wassermann reaction," either possesses no exact meaning whatever, or, if it is intended to convey the impression that cholesterin merely produces an increased anticomplement effect in every instance, then the authors are demonstrably wrong so far as the conditions are concerned under which we have employed cholesterin in the Wassermann reaction.

There is a grave error into which a certain attitude of mind leads some observers; they generalise from the results of a single type of experiment, and without hesitation condemn a long series of carefully planned and adequately controlled observations. A comprehensive knowledge of experimental work in the domain of immunity should guard against such rash generalisation. As an example of the necessity for avoiding generalisation I would quote the following example: Thiele and Embleton find that the delicacy of the Wassermann reaction is increased in their hands when they use large amounts, half a cubic centimetre or more

Table illustrating the Effect of Antigens containing Cholesterin.

Serum (55° C. for ½ hour) 0·05 c.c.	Turbid emulsion of antigen 0·6 c.c. (a) Ox-liver lecithin 0·75 per cent. in absolute alcohol, 1 part emulsified with saline 7 parts. (b) Ox-liver lecithin 0·75 per cent. + cholesterin 1 per cent. in absolute alcohol, 1 part emulsified with saline 7 parts.	Doses of guinea-pig's complement.				
		3½	5	8	11	16
A.—Medium strength positive serum.	(a) + Lecithin.	Trace.	Very marked.	Almost complete.	—	—
	(b) + Lecithin-cholesterin.	0	0	0	Faint trace.	Almost complete.
B.—Powerful positive serum.	(a) + Lecithin.	0	0	Trace.	—	—
	(b) + Lecithin-cholesterin.	0	0	0	0	0
C.—Negative serum.	(a) + Lecithin.	Just complete.	Complete.	Complete.	—	—
	(b) + Lecithin-cholesterin.	,, ,,	,,	,,	Complete.	Complete.

Controls—

Emulsions alone, 0·6 c.c. (a) Lecithin + 3 doses of complement = just complete.
(b) Lecithin-cholesterin + 3 ,, ,, = ,, ,,
Sera alone 0·05 c.c. + 0·6 c.c. saline Serum A + 1⅓ ,, ,, = complete.
,, B + 1⅓ ,, ,, = ,,
,, C + 1⅓ ,, ,, = almost complete.
Dose of complement = 0·015 c.c.

Note.—The results indicate the amount of hæmolysis of 1 c.c. 5 per cent. washed ox-blood suspension sensitised with 5 doses of immune body from the rabbit.

of inactivated syphilitic serum. Now, Gilmour, working according to the method of Browning, Cruickshank, and McKenzie (*v.* Browning and McKenzie,[10] p. 84), found that there were very definite disadvantages attendant on the use of such large amounts of serum, among which may be mentioned the marked inhibitory effect of such a quantity of heated serum by itself on complement.

To sum up. Accuracy and delicacy in performing the Wassermann reaction may be attained by attention to the following points:—

1. The accurate measurement of the amount of complement absorbed by the mixture of (heated) serum and of antigen, estimated in hæmolytic doses, and controlled by an estimation of the amount of complement inhibited by each component separately. To effect these estimations requires for each serum six or seven tubes in addition to three tubes to control the action of the lipoid emulsion. Such a procedure enables the observer to place the greatest confidence in his results, and it is to be regretted that some workers do not consider it worth their while as a routine practice to expend the time required to attain such accuracy.

2. No method can be satisfactory which neglects the fact that complement is not an invariable quantity. Not merely do different guinea-pigs yield serum with varying hæmolytic power for sensitised blood corpuscles, but the deviability of two complement-containing sera with the same hæmolytic dose may show a wide difference. Such differences in deviability of complement are observed both when sensitised ox and sheep corpuscles are used as the test. To control these variations known negative and positive sera, whose behaviour has been determined in previous tests, should be included in every series. An average specimen of complement can be obtained with some degree of certainty by using the pooled serum of several guinea-pigs. Recently we have employed the pooled sera of 10 or 12 animals, separated by centrifuging the switched blood immediately after withdrawal, and pipetting off the mixed serum into a series of small bottles which are then placed in a refrigerator and the contents kept frozen hard at minus 12° C. The serum required for a test is allowed to thaw and is then kept in the ice chest for about 16 hours before use. We have found that under these conditions the hæmolytic power and the deviability of serum remain practically unaltered for at least six weeks. This procedure seems to offer the best method for preserving for a considerable length of time a standard specimen of complement (Browning and Mackie[17]).

3. The test corpuscles should be sensitised to the maximal degree by the addition of at least five doses of specific immune serum (from the rabbit). In this way disturbances due to variations in the normal immune body content of the patient's serum or the complement-containing serum can be obviated.

4. The "antigen" should by itself possess little hæmolytic or anticomplement action, a point which Browning and McKenzie emphasise.[10] Antigens which are highly satisfactory in these and in other respects can be obtained by employing alcoholic mixtures of cholesterin with certain other tissue lipoids. The antigenic property of many lipoid tissue constituents—e.g., "lecithin" from heart and liver, crude alcoholic extracts of heart, &c.—can be increased by the addition of cholesterin to the alcoholic solution. In the case of "lecithin" from ox liver, personal experience has shown that the addition of cholesterin increases the power of the lipoid emulsion to lead to complement-fixation along with syphilitic serum. Along with normal serum, on the other hand, no such increase occurs, and at the same time the cholesterin does not increase the anticomplement effect of the lipoid emulsion by itself. Accordingly, cholesterin possesses a remarkable specific action in the presence of syphilitic sera together with certain tissue lipoids; this effect of cholesterin has proved of great practical value in eliciting the Wassermann reaction.

POPLITEAL ANEURYSM.

BY H. BETHAM ROBINSON, M.S. LOND., F.R.C.S. ENG.,
SURGEON AND JOINT-LECTURER ON SURGERY AT ST. THOMAS'S HOSPITAL; EXAMINER IN SURGERY IN THE UNIVERSITY OF LONDON.

POPLITEAL aneurysm, which 30 years ago was so frequently seen in our hospital wards, and the treatment of which by digital compression—the method then much in vogue—has left a lasting impression, is now comparatively a rare disease. A considerable revival of interest in the treatment of this lesion has been aroused by the introduction by Matas of his methods of dealing with the sac, which have been fully discussed recently in the Surgical Sections of the International Medical Congress and of the Royal Society of Medicine.

Whatever may be the method of treatment selected, the aim and object is the obliteration of the sac. Matas secures this obliteration by opening the sac and suturing from within the main vessels and the smaller feeding ones, afterwards suturing and doubling up the sac wall, or he adopts his more conservative measures devised to preserve the lumen of the vessel, at the same time obliterating the sac. These procedures, brilliant and successful as they have proved, will in dealing with popliteal aneurysm not easily supplant the older highly tried methods, and probably will have a more limited application. The Hunterian operation, with its simplicity of technique and very small percentage of permanent recurrent pulsation, will with many still hold the field. In those doubtful cases of threatened gangrene or with local inflammation about the sac, ligature, whatever may be the outcome, would probably without doubt still seem the best method to adopt.

The first case described below illustrates what that success may be under such unpromising conditions as were there present—a large sac, ill defined, with local inflammation and effusion into the knee-joint, and œdema of the leg below. There seemed so strong a probability of gangrene ensuing that amputation was seriously considered, which the patient, a man of fine physique, would not agree to. After consultation with my colleague, Mr. C. A. Ballance, it was decided to ligature the vessel and afterwards to deal locally with the aneurysm should success be attained, which fortunately was the sequel.

The second case is an example of the ideal and most certain method of obliterating the sac by excision, a procedure limited by the size of the aneurysm and the condition of the surrounding tissues. Exception has been taken to its employment for popliteal aneurysm because of the likelihood of damaging a possible adherent popliteal vein or the anastomosing vessels. If the aneursymal sac is of moderate size and apparently well defined, these difficulties may be non-existent or surmounted. For such cases this radical procedure has a place and may be used successfully.

CASE 1. *Left popliteal aneurysm; fluid in the joint; ligature of the superficial artery at the apex of Scarpa's triangle; later incision into the sac and removal of clot; recovery.*—The patient, a South African negro, aged 26, was admitted under me on Oct. 7th, 1911. Towards the end of 1909 he had tingling pain in the popliteal space, but of this he did not take very much notice. In October, 1910, he first noticed a lump here; this was thought to be due to rheumatism and he had massage. The swelling, however, gradually increased in size, and there was difficulty in straightening the leg and in walking about; owing to the severe pain for several weeks before, he sought admission. There was no history of syphilis, but thickening of the tibiæ strongly suggested it. In the left popliteal space was a very prominent pulsating swelling, the pulsation in which was effectually stopped by compressing the femoral. The leg below was generally swollen and the surface veins distended; there was some œdema around the ankle and also over the back of the knee-joint. The knee-joint contained fluid, and there was very limited extension of the leg; there was some dropping of the foot, and on inquiry his pain had been particularly referred to the external popliteal nerve area; there were also several large scars, not very deep, in the middle of the leg on the outer side. The heart and arteries were healthy. Over the most prominent part of the swelling the measurement was 19 inches; 6 inches above the knee 17 inches; and over the middle of the calf 15 inches.

The unsatisfactory condition of the limb raised considerable doubt as to the likelihood of saving it. The embarrassed return circulation and swelling behind the knee pointed to the strong probability of gangrene occurring should any other treatment but amputation be attempted. It was decided, however, to try to save the limb, so the superficial femoral artery was ligatured at the apex of Scarpa's triangle on Oct. 13th. After ligation in two places and dividing the vessel between it was noticed that there was little, if any, reduction in size of the aneurysm. On the next morning (14th) the limb was fairly warm, but no definite pulsation could be felt in the tibials; the patient complained of cramps. On the 16th the collateral circulation was well established; the limb was warm, and faint pulsation could be felt in the tibials, but the size of the aneurysm was not appreciably reduced, measuring 18½ inches. The subsequent progress may be summed up as follows. There was complete restoration of the circulation in the tibials and loss of the fluid in the joint, so that all bone outlines were distinct, but the aneurysm remained of the same solidity and size. The pressure effect on the external popliteal nerve, as shown by foot-drop and wasted muscles, became more definite, and massage and galvanism were used. On Dec. 5th the measurement, made as before, was reduced to 17 inches, but this could be partly or wholly explained by the absorption of the fluid in the joint. The aneurysm was for the most part quite firm, but on its outer side there was a fluid collection. The man then wished for his discharge, but continued to attend as an out-patient for massage and galvanism.

The patient was readmitted on Jan. 16th, 1912, with the aneurysm of the same size and consistency and without pulsation. There were still the signs of involvement of the external popliteal nerve with rather more anæsthesia; the foot was more pointed from contraction of the calf muscles. On Jan. 31st I made a vertical incision down on the sac and very easily exposed it. It was then freely opened and a large quantity of both laminated and dark clot was removed and the sac completely emptied. There was no bleeding from the sac wall, so after washing it out with saline the wall was doubled down as well as possible and stitched with catgut, thus greatly reducing the empty space. Primary union took [illegible] followed by a marked reduction in [illegible] became localised in two [illegible] on the outer side of the leg and foot. The movements at the knee became more free, and it was then noticed that limitation in extension was due to some dropping back of the tibia, the result of softening of the crucial ligaments brought about by the pressure of the aneurysm on the back of the knee-joint which had been also shown by the synovial effusion. Massage and galvanism were continued, but as the ankle-joint movements remained very limited the joint was first wrenched under gas; as this did not result in much improvement the tendo Achillis was subsequently divided. Further exercises gave a much better range of movement at both knee- and ankle-joints, and the man when last seen had a quite useful limb.

CASE 2. *Left popliteal aneurysm; excision of the sac.*—The patient, aged 46, was admitted under me on July 15th, 1909. There was no history of syphilis and no evidence of cardiac or arterial disease; he had had rheumatic fever 20 years before. His general health had always been good, but latterly he had felt weak. Six months before he first felt pain in the left knee with pain shooting down the outer side of the leg; the pains continued, and during the about in the course of the second week after the accident, and sometimes even earlier.

The appliances are made at the Veifa works, Frankfort/a/Main, and can be obtained through all surgical instrument makers.

Wiesbaden.

RECURRENT INTUSSUSCEPTION:

WITH SUGGESTIONS AS TO THE ETIOLOGY.

BY H. TYRRELL GRAY, M.A., M.C. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON, WEST LONDON HOSPITAL AND HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; SURGEON, WEST HAM AND EASTERN GENERAL HOSPITAL, ETC.

IN view of the rarity of recurrent intussusception recently commented upon in THE LANCET, and after reading the report of Mr. G. Grey Turner's interesting case,[1] I thought it might be of interest to place on record the notes of the following case.

On May 25th, 1909, a male child, 2 years and 1 month of age, was brought to hospital with the following history. Two hours previously he had a screaming fit, and half an hour later passed blood and mucus per rectum. The child vomited shortly after arriving at the hospital. A typical sausage-shaped mass could be felt in the upper abdomen. On two occasions previously this child had been operated upon for intussusception by another surgeon, and on each occasion recovery was uneventful. The details are as follows. In March, 1908, laparotomy revealed a typical ileo-colic intussusception which was reduced, the abdomen being closed in the usual way. The wound healed perfectly and convalescence was uninterrupted. In October of the same year the abdomen was again opened, and an intussusception was found which had started at the cæcum. Reduction was effected as on the first occasion, and again recovery ensued. On this occasion, however, the mobile cæcum was fixed by sutures.

In May, 1909, I opened the abdomen under spinal anæsthesia and reduced the intussusception, which on this, the third, occasion was enteric in type and was situated some little distance from the ileo-cæcal valve. Under spinal anæsthesia intestinal peristalsis continues unhampered by the inhibitory stimulus of the operation, and during the examination of the intestine an intussusception started, *for the fourth time*, in a coil of gut in my hand. Nothing abnormal was discovered in the abdomen which could account for the tendency in this child for intussusception to develop. Recovery was again uninterrupted, doubtless owing to the promptness with which the mother, by this time well acquainted with the symptoms, sought surgical aid.

The great interest of this case lies in the fact that on each occasion the intussusception started at a different part of the intestine. And this seems to me to raise again the question as to the etiology of the condition. In Mr. Grey Turner's case the intussusception started at the lower end of the ileum on each occasion, and he found a definite lesion to account for the tendency to recurrence. In my case no such explanation could be discovered; in fact, the recurrence seemed quite inexplicable.

Presupposing that infants (in whom the mesentery is exceedingly elastic and pliable), and subjects who have a congenitally long mesentery, are liable to develop intussusception, we are still left with the task of finding an exciting cause. Irregular peristalsis has been quoted as a factor; and this may, perhaps, be of some importance in cases where a persistent Meckel's diverticulum is present to interrupt normal peristalsis. On other occasions an inverted diverticulum, acting as a polyp, may be responsible, as in one of my cases already reported.[2] Such cases, however, are rare. FitzWilliam has shown, in a statistical review of 1000 cases, that *diet* is certainly the most important causative factor in the majority of cases. Whereas errors in diet usually cause enteritis, it is not difficult to believe that wrong feeding in infancy, not sufficiently gross to set up acute enteritis (inflammation of the mucous membrane), may yet cause chronic inflammation of Peyer's patches. Finally, a glaring error of diet causes acute congestion and swelling of this lymphoid tissue, which bulges into the lumen of the gut; such a swelling would act in the same way as a polyp, and intestinal peristalsis would tend to drive it along the canal with the intestinal contents. Where the mesentery is elastic or unusually long, an intussusception would be likely to result.

Such a view is supported, perhaps, by the uniform presence of a mass of enlarged mesenteric glands in the neighbourhood when the intussusception starts at the lower end of the ileum. These glands seem to be enlarged whether the abdomen is opened soon after the onset no less than when there has been considerable delay. Further, glandular enlargement is not a feature to anything like the same extent, I think, in enteric intussusception. The inference seems to be that the glandular enlargement precedes the intussusception, and is caused by infection from the Peyer's patches. The frequency with which intussusception starts at the lower end of the ileum and the fact that *diet* is responsible in the majority of cases seem to support the following view. That inflammation and swelling of Peyer's patches (usually the result of errors of diet) are responsible for the onset of intussusceptions starting at the lower ileum; but that these factors leave unexplained the origin of intussusceptions starting at other situations in the intestinal tract.

I have recently shown[3] how general infections may cause intestinal colic; that both acute and chronic general infections might be responsible; and in that paper I quoted cases in support of the statements made. Without again entering into detail it seems reasonable to suppose that acute general infections, which may cause effusions in the skin and subcutaneous tissues and in other regions, may also be responsible for effusions into the intestinal wall. I suggested that such an effusion, by preventing the proper contraction of the intestinal muscle in its vicinity, creates an *inert area* in the bowel wall. The bowel wall being comparatively insensitive, there is no pain arising directly from such a lesion; but such an inert area constitutes, as it were, a "foreign body" in the intestinal wall; and this affected piece of bowel tends to be driven along the canal (with the intestinal contents) in the same manner as an intestinal polyp or the inflamed Peyer's patches already referred to. The result is that *during peristalsis* the mesentery is dragged on by the efforts to drive along this portion of bowel and typical *colicky pain* results. In acute rheumatism such an effusion sometimes reaches a size sufficiently large to rupture the mucous membrane, when hæmorrhage from the bowel results; the condition is then known as "Henoch's purpura." I have encountered a similar condition in diphtheria. The effort made by the muscular action of the intestine to drive along the canal such inert areas as I have described will, when anatomical conditions are propitious, actually invaginate the bowel wall at such a situation and *intussusception results*.

---

[1] THE LANCET, Dec. 20th, 1913, p. 1785; Jan. 17th, 1914, p. 169.

[2] Annals of Surgery, 1908.

[3] Practitioner, January, 1914.

The association of such inert areas with the onset of intussusception draws our attention to the relationship of this affection with acute general infections. And I wish to offer again the suggestion that *acute general infections* are often responsible for the onset of intussusceptions other than those starting at the lower ileum; and perhaps in some of these where error in diet (or other causes) can be excluded. Such a view explains the occurrence of intussusception in more than one member of a family—doubtless a fairly common experience. And this explanation is the one which I am inclined to offer for the recurrence in three different situations in the case I have just reported. I have seen the undoubted association between acute rheumatism and intussusception, and do not doubt the possibility of other infections playing a similar rôle.

The importance of realising such a cause of intussusception lies in the fact that, after treating the acute condition, we ought to make every effort to find and remove the cause. If there are enlarged glands in the mesentery, and the intussusception starts at the lower ileum, *diet* should be suspected as a cause. Careful inquiry may elicit an exciting cause; but, if not, a search should be made for evidence of a general infection. When the intussusception starts high up in the ileum the possibility of a persistent Meckel's diverticulum, or a solitary intestinal polyp (arising from the invagination of a diverticulum), should be borne in mind and looked for as an exciting cause. When these are absent, or when the intussusception starts in the cæcum, I believe the blame may often be laid at the door of an *acute general infection;* and the source of such an infection should be carefully sought and treated when the child has recovered.

Recently I operated in the following case for intussusception:—

The patient was a male child 10 months of age. The history was obtained that three days previously the child was feverish and the parents thought he had a sore throat. The medical attendant diagnosed a "feverish chill." On the day of admission to hospital a screaming attack preceded the passage of blood per rectum, and the child became *very drowsy*. Though there had been no vomiting retching had been noticed on one or two occasions. When the child was in the ward drowsiness was a marked feature of the case.

On examination of the abdomen a typical mass was felt in the left flank which made the diagnosis perfectly clear. *On examination of the neck* a large mass of enlarged discrete glands was found to be present on both sides, while inspection of the throat showed that the glandular enlargement was secondary to inflammation of the very large and reddened tonsils.

I expected to find an intussusception *starting in the cæcum* in this child; and, on opening the abdomen under spinal anæsthesia, this proved to be the case. There was no marked glandular enlargement such as is usually met with when the lower ileum forms the starting point.

Now I feel sure that the "feverish chill" owed its existence primarily to tonsillar infection, the cervical glands being secondarily enlarged; and that the resulting "general infection" was responsible for the onset of intussusception in a child whose large bowel was exceedingly mobile. In order to remove the source of infection in this case the tonsils should be completely dissected away by Waugh's method, and this I intend to do as soon as the child has completely recovered from the effects of the laparotomy. I do not believe there is any need to fix the cæcum as a preventive measure, since, if the primary cause remains untreated, recurrence may take place in some other situation (as in the case I have reported). Also, in these cases, no more should be done than is absolutely necessary. As long as the primary cause is treated, by medical or surgical measures according to the indications, not only will there be little chance of recurrence, but other undesirable consequences of an untreated general infection will also be avoided.

Harley street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE VALUE OF PITUITARY GLAND SUBSTANCE IN SOME CASES OF ASTHMA.

By F. G. CROOKSHANK, M.D. LOND., M.R.C.P. LOND.,
PHYSICIAN (OUT-PATIENTS), NORTH-WEST LONDON AND HAMPSTEAD GENERAL HOSPITAL; ASSISTANT PHYSICIAN, BELGRAVE HOSPITAL FOR CHILDREN.

EVERYONE is of course now familiar with the immediate success that generally attends the hypodermic administration of adrenalin or hemisine in paroxysms of true asthma; but unfortunately the gratification afforded by the production of the striking result is almost equalled by the disappointment due to its relative transience. It is, however, less well known that many patients who are benefited, during attacks, by the administration of the drug hypodermically will also obtain considerable advantage if the same drug is given by mouth regularly in tablet form.

I have employed it in this manner for weeks at a time with advantage and, so far as I have been able to ascertain, without detriment. It is true that many observers, on the strength of experimental findings, fear the development of arterio-sclerosis as a result of the long-continued use of suprarenal derivatives; yet on the whole it is a safe clinical maxim that the exhibition of drugs which supply a physiological need is not attended, if properly given, by the unpleasant consequences that may follow their experimental use when not indicated therapeutically. Recently, however, it occurred to me that it might be worth while, for obvious physiological reasons, ascertaining the effect of pituitary substance, if given regularly, in cases of asthma. For the last six months, therefore, I have treated a certain number of adult patients that I have seen suffering from asthma with two-grain tablets of pituitary gland substance, taken each night and morning. About 20 such patients have been so treated, and the results seem worthy of report.

Without exception each one of the patients so treated has expressed himself or herself as greatly benefited; the attacks have been far fewer and less severe, while the general health has in most cases improved considerably. Two points are rather striking. The majority of the patients so treated have ceased to ask for their accustomed stramonium powder for burning and inhalation; and of those who, feeling as they have said much better for the tablets, ceased regular attendance, every one has come back asking for more, as being not so well without them.

I have not yet given the preparation to any children with asthma, for in children the use of other remedies is generally so satisfactory. But some uniform throughout, and it was much more adaptable because it was able to be condensed. Several varieties of screens were used and included 1/100 mm. of aluminium, 5/100 mm. aluminium, 0·5 mm. silver, 1 mm. silver, 1, 1·5, 2, and 3 mm. lead, and 0·3 and 0·5 mm. platinum. Of these he preferred the 1 mm. silver screen. If too thick a screen were used, secondary radiation occurred. Speaking of the protection of healthy tissues, he said that he had found in cases of application of radium to the axilla that ill-effects were particularly likely to occur if the axilla was moist. This was combated by drying with dusting powder. In applying radium to a tube of mucous membrane, as the rectum or vagina, the healthy mucous membrane might be protected with a gauze plug. A flexible silver wire was a useful means of keeping the tube in position. Whenever it was possible to bury the tube in a growth to be treated this should be done, for in this way the degree of emanation utilised was at least four times as great. He then spoke of the experience which he had met with in the treatment of various forms of disease. In the case of capillary nævi a preliminary diascopy was useful. If by gentle pressure blanching was caused the result of treatment would probably be good. There was considerable personal idiosyncrasy to treatment, and it was important to gauge the personal equation first and not to keep irritating the skin lest telangiectasis and pigmentation be produced. Venous nævi reacted successfully, except when a pulsating vessel could be felt. He also spoke of the use of this treatment in certain diseases of the skin—pruritus, lichenification, chronic eczema, psoriasis, lupus erythematosus, keloid, and keloid acne. Pruritus was successfully treated only if it was associated with definite lesions. Psoriasis improved, but the rash returned. Keloid and keloid acne were benefited more than by other methods of treatment. Warts often disappeared after one exposure, but moles were not benefited to the same extent, and a scar often remained. The treatment was suitable for tuberculosis of glands in the absence of operation, but tuberculosis of skin did better by the Finsen light. Fibromyomata of the uterus had been treated by 100 milligrammes in the vagina or cervix, and 100 more on the lower abdominal wall. No result followed at first, then the metrorrhagia ceased, and, finally, the menorrhagia. From the point of view of radium therapy, rodent ulcer presented two types: (1) the hypertrophic nodular type, which was almost certainly cured by radium; and (2) the ulcerative type with overhanging edges and gelatinous base, which was not so favourably influenced by the treatment. He then spoke of radium therapy in relation to malignant disease. The treatment for malignant disease which was operable was by operation. He did not use the word "cure" for the results of radium treatment in relation to new growth. In carcinomata of the tongue and mouth there had been some encouraging results by the use of small and powerful tubes. Carcinoma of the œsophagus had been temporarily benefited, but he had not seen a case of arrest of the growth. The annular type of carcinoma of the rectum was influenced more than the plaque variety of growth. Some very good results had followed treatment of carcinoma of the bladder, and he had seen no results equal to those obtained by radium, operation excepted, in carcinoma of the uterus. When in this disease a Wertheim's operation had been done it was necessary to exercise great care in the treatment. Improvement had been noticed in the treatment of new growths of the prostate and of the penis. The neoplasms which responded best of all were the sarcomata, particularly those in the naso-pharynx, and the lympho-sarcomata. Melanotic sarcoma was best left untreated by this means. In lymphadenoma great and rapid temporary improvement had followed. Neuritis due to local lesions had been benefited. The variety of arthritis deformans which gave the best results was that which was multi-articular in character and peri-articular in form. It was incumbent upon all of them to exercise the greatest caution in the publication of their results, and more especially of statements which might afford an opportunity for distortion by the lay press. The effects of garbled announcements in the daily papers were often most tragic, and the amount of mental distress caused to patients and their relatives when they were informed of the true position of affairs was incalculable. He could find it in his heart to wish that all workers with radium might be pledged to a policy of silence for two years, and though this was impossible he could at any rate urge the deletion of the word "cure" from their vocabulary when speaking of the radium treatment of malignant disease. They must all most earnestly hope, however, that the time was not far distant when, with increased knowledge and improved technique, they might be able to use the word "cure" deliberately and justifiably. That they did possess in radium a therapeutic agent of great power no thinking medical man could deny, but exactly how powerful it would prove to be was at present a matter of conjecture. Many years ago the eminent philosopher and scientist, Sir Isaac Newton, in reviewing the work of his life, said: "I seem to have been only like a boy playing by the seashore and diverting myself in now and then finding a smoother pebble or a prettier shell than ordinary, whilst the great ocean of truth lay undiscovered before me." He hoped his hearers would pardon him if he adopted that simile and said that the present-day workers with radium were but as beach-combers searching earnestly and persistently, finding here the valuable agate of hard fact, and there the precious shell of some delicate inference; but the treasures of the ocean of radium therapy lay unexplored before them.

Sir FREDERICK TREVES said that the position of radium was peculiar, for it had controverted acccepted laws both in physics and in chemistry, and exhibited no feature which was not marvellous. It had often been said that radium stood at a very excessive and artificial price, and that, commercially speaking, a corner in radium existed, but there was no truth in this statement. The price was due entirely to the demand. He expected that it would become cheaper, but would never be cheap. There was a prospect of using additional sources of supply. As the result of the great demand for it much so-called radium was of very inferior quality. Terms of amount which were frequently used in radium therapy were of no value, as the strengths varied greatly and there were many different salts, each containing a different percentage of the metal. The technique which had been employed at the Radium Institute was that laid down by Wickham, but, as that observer had indicated, there was every probability that the technique might be improved. He agreed entirely with the closing part of Major Pinch's address.

Sir ALFRED PEARCE GOULD said that he also appreciated the caution advised by the opener, that little should be said of the curative value of radium for the present. He agreed that the introduction of radium into growths was much better than its application to their surfaces, and recounted a case of a tumour of the brain of a girl to whom decompression had been done. A large mass projected through the skull, but whether of cerebral tissue or glioma it was impossible to say. After the introduction of radium she had recovered speech and memory and had been able to give an account of herself. The improvement lasted three weeks, but her stuporose condition then recurred and she died. One could not speak of any remedy for cancer by the name of "cure" until one knew the nature of the condition.

Mr. A. CLIFFORD MORSON spoke of his researches into the histological appearances of new growths after radium treatment. The malignant cells underwent degeneration, not only in the growth itself, but also in the glands secondarily affected.

Dr. HERBERT WILLIAMSON spoke of the use of radium in diseases of the female genital organs. He had had experience in cases of carcinoma of the cervix, carcinoma of the body of the uterus, fibromyomata, and fibrosis uteri. In carcinoma of the cervix he had operated first, and within two or three days afterwards applied radium through the vaginal wound which had been left open. His object had been to subject to the emanations the outlying cancerous tissue. It was too early to judge of the results. Only inoperable cases had been treated by radium. He had not seen a case either cured or rendered operable, but the patients' lives had been prolonged, and considerable improvement had followed. In every case, however, a sudden and unexplained outburst of carcinoma had taken place later. In carcinoma of the body of the uterus the results had been better, and he thought that one case had become operable by this means. He had only employed it for fibromyomata where operation was contra-indicated, and had treated two cases in which no uterine hæmorrhage at all had followed.

The question of cure in such cases should be postponed, but he was convinced that in radium the surgeon had a powerful aid which should be called in as soon as possible after operation

Mr T H KELLOCK said that he was in agreement with nearly everything which Major Pinch had said He mentioned that radium treatment might produce harm, and called attention to the necrosis and destruction which might result in healthy tissue He had seen necrosis of bones, and especially of the jaw, after the application of radium an eventuality which might sometimes be deferred for weeks or even months It was necrosis of a very severe form He had observed the same effect upon the mucous membrane of the mouth which was comparable to that produced by X rays Many of the cases which were especially benefited were those in which sepsis and cancer were combined, and he thought that in such one ought not to draw too definite a *conclusion as to the effect on the cancer itself* He doubted whether radium ought only to be used for inoperable cases, and did not think it a rational procedure to use radium after the growth had been removed

Mr DOUGLAS HARMER said that radium had proved of great value in the treatment of cancer of the upper respiratory tract and that the following considerations were important 1 Method of application Tubes containing 100 to 200 milligrammes should be buried deeply in the growth, if possible, from outside by an aseptic operation The normal mucosa must be protected from burning For cancer of the mouth or pharynx as much of the growth as possible should be removed by diathermy before applying the radium The tubes might be left in place for 12 to 48 hours, according to the size and situation of the growth, large doses and prolonged treatment were followed by considerable sloughing 2 Effects produced (*a*) Shrinking *of the growth was often rapid, and was obvious a few days* after exposure If no result was noticed in three weeks the case was not a favourable one (*b*) Arrest of hæmorrhage Radium was valuable for this purpose, for instance bleeding from a cancer of the tonsil could sometimes be checked completely by an application of a few hours (*c*) Pain When the growth disappeared or became smaller pain might be completely relieved, on the other hand radium might increase the pain, and this constituted one of the great drawbacks to the treatment in very advanced cases 3 Results In most cases improvement was only temporary, but in rare instances it might last for months or even years The best results were seen in cases of rapidly growing sarcoma, such as occurred in the nasal fossa, upper jaw, post nasal space or tonsil As operations on such tumours were so often followed by rapid recurrence the question of radium in preference to the knife should be carefully considered Growths which appeared to be microscopically sarcomata might completely disappear after radium Carcinoma of the upper jaw or nasal fossa might also shrink away quickly and remain quiescent for a period and hard warty growths on the tongue, tonsil, floor of the mouth or pharynx were rarely improved He had not yet seen a cancer of the tongue or tonsil which had been cured by radium Epithelioma of the deeper pharynx and œsophagus could sometimes be retarded by radium and dysphagia might be relieved for a time Ulceration might disappear, so that expectoration of foul discharge was lessened Greater activity of the growth was rare Endothelioma was said to improve but in two of his cases the radium had little effect The important question arose whether radium should be placed in wounds when it was found that the whole of a growth could not be removed with the knife and for how long the treatment should be continued There seemed no conclusive evidence that radium would retard the growth in some cases Certain innocent tumours could be cured by radium At the present time he had under treatment a case of multiple papillomata of the larynx which was steadily getting better Previously the man had had repeated operations during ten years Harris, of New York, reported 13 cases of the same kind cured by radium with better voice results than would have been obtained by operations

Dr N S FINZI referred to the factors which influence success or failure in the radium therapy of malignant disease 1 The most important factor was the type of growth The more rapid the growth the more likely was it to respond readily, and the more vascular growths were also more favourable The round celled sarcoma was the most amenable to treatment, and he advised radium treatment of this disease in preference to surgical eradication, the other sarcomata were also favourable but to a lesser degree The columnar carcinomata responded better than the epitheliomata and in some cases, particularly uterine carcinoma they responded very well indeed The epithelioma of the *maxillary antrum* was an exception to the general rule of epithelioma and responded readily The endothelioma also reacted favourably 2 Stage of the disease This was most important as the action of the radium was due, in part at any rate, to the action of the healthy tissues *in destroying the disease In the later* stages of the disease the patient's resistance went and radium would do no good 3 The method of application (*a*) It was essential to treat the disease thoroughly as well as the outlying parts Excessive radiation causing sloughing of healthy tissues *was to be avoided* (*b*) Frequency of repetition As a rule applications were used at intervals of six to eight weeks, and it was better to use long applications at long intervals than short applications at frequent intervals (*c*) Type of rays In his experience the γ rays were the most useful type He usually employed 2 mm platinum to screen the rays in most forms of malignant disease (*d*) It was necessary to use large quantities of radium in dealing with this complaint He agreed with Major Pinch as to the advisability of burying the radium in a growth whenever possible Not only were the rays in all directions utilised but one also obtained rays of very great intensity close to the tube He was using another method which he suggested in 1909 Instead of burying the radium in the growth it was buried in the tissues around it close to the growing edge The method was only available in a few cases, but as the growing edge was all that really mattered *in a growth the method had distinct advantages* It also led to a considerable amount of occlusion of the vessels and lymphatics around the growth This was most desirable, as it caused retrogression It was essential in all these embedding operations to practise the *most rigid asepsis* the damaged tissues forming an excellent breeding ground for bacteria if they were allowed to enter A variant of these operations was to introduce radium not into the centre of the growth, but under the growing edge or in a groove in the growth

Dr H LEWIS JONES emphasised the importance of detailed study of the after histories of cases that had been treated by radium

WEST LONDON MEDICO CHIRURGICAL SOCIETY

The Treatment of Syphilis of the Central Nervous System

A MEETING of this society was held on March 6th, Dr F S PALMER the President being in the chair

A paper was read by Dr HARRY CAMPBELL on the Treatment of Syphilis of the Central Nervous System He said in the treatment of the interstitial forms of syphilis of the central nervous system gummatous meningitis endarteritis, &c, good results could be obtained from the use of mercury and potassium iodide and salvarsan, the mercurial course must be thorough and the dose of iodide large 1–2 drachms or more of the latter three times a day In the parenchymatous forms of the disease general paralysis of the insane and tabes dorsalis, no drugs were of use because the coverings of the cord and brain did not permit their passage In 1900 intrathecal injections of mercury into the spinal canal were first tried Two years ago injections of salvarsanised serum were injected into the spinal canal, in nearly every case of tabes dorsalis where this treatment had been adopted improvement occurred The lightning pains have in each case been relieved in nearly all the Wassermann reaction has become negative while the leucocytosis has improved and the patient put on weight very rapidly Cases of general paralysis have not been improved, but in two cases recently where the serum has been introduced into the lateral ventricle there has been some improvement

Dr PALMER said From the large amount of research in recent years into the pathology of syphilis of the central nervous system there is stro
that the infection is in every
of the brain and cord, and

deserved careful study. It must be remembered that a genuine secondary dermatitis might be set up by scratching and might mask the original artificial eruption, also that a genuine pre-existing skin disease was sometimes wilfully aggravated and kept up by patients who profited by continued disability. On the other hand, a particular occupation might have been followed for years without the skin suffering, and yet from lowered vitality or other causes the skin resistance might give way and a true dermatitis ensue. For the detection of simulated unilateral blindness an ingenious test has been invented by Dr. von Haselberg, of Hamburg, consisting of parti-coloured letters and figures used in conjunction with red and green glasses. It was based on the fact that anything coloured red could not be distinguished as red if looked at through a red glass. To be successfully applied the test must be carried out with great caution. One of the most difficult things in medico-legal medicine was to state with any degree of accuracy the amount of disability resulting from impairment of the hand as a whole or any of its digits separately or together. This difficulty was enhanced by the invariable habit patients had, when being examined with a view to fitness for work, of involuntarily watching every movement they were asked to make, with the result that the malingerer consciously, and the honest man unconsciously, restrained all movement. No real information could be gained unless the patient's view was entirely obscured, either by a book or newspaper held in front of his eyes, or better by blindfolding of his eyes. By various devices also a malingerer might be taken off his guard and led to execute movements of which he had professed himself quite incapable. Loss of substance, the result of sloughing or suppuration of ulcerated wounds, when it took place in large muscles, sometimes produced an unsightliness out of all proportion to the diminution of power resulting from the accident. It was not infrequent, therefore, to find that during the process of healing, which was necessarily slow, a man had consciously or unconsciously been directed by actual loss of tissue to exaggerate the resulting disability. It was not unnatural for a layman to associate loss of substance with corresponding loss of function, making no allowance for the surplus power with which nature had lavishly supplied us, and this was exactly the class of case in which the judicial authorities, if unassisted by a medical referee, were apt to sympathise unduly with the plaintiff.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.—A meeting of this society was held on Feb. 25th, Dr. J. Coubro Potter being in the chair.—Dr. Potter exhibited a case of Retro-Pharyngeal Abscess in a woman with secondary abscess in the axilla. Owing to the serious condition of the patient a preliminary laryngotomy was performed and the upper end of the larynx plugged. The abscess was then evacuated. Recovery was uneventful.—The case was discussed by Mr. C. J. Heath, Mr. W. Ibbotson, Dr. Frederick Spicer, and Mr. Haynes Lovell, who thought that possibly the axillary abscess was primary and not secondary.—Dr. Potter, in reply, said he looked upon it as an acute exacerbation of a chronic condition, possibly arising from tuberculous prevertebral glands. The fact that no tubercle bacilli were found in the discharge did not negative tuberculosis. He also showed a case of severe Tinnitus in a woman with suicidal tendencies.—Mr. Heath showed two patients on whom he had performed mastoid operations in order to prevent deafness, and subsequently read notes on a mastoid case in which delay of operation caused prolongation of the danger by weeks and the after-treatment by months.—Dr. Spicer pointed out the great difficulty of the general practitioner in making a decision as to the necessity or otherwise for a mastoid operation. He thought that the indications for operation required revising. He could not quite agree with the dictum of Mr. Heath, "that a persistently discharging ear without pain means danger to hearing and a discharging ear with pain danger to life." According to that view every discharging ear ought to be operated upon. He hoped Mr. Heath would clearly state what he considered were the indications for performing a mastoid operation.—The cases were also discussed by Dr. Potter and Mr. J. Walker Wood.—In reply, Mr. Heath pointed out that the treatment must depend upon the aural surgeon's ideal. If his ambition extended to the prevention of deafness from aural suppuration, he must arrest discharge before it had done harm to the tympanic apparatus, and this frequently entailed the performance of a conservative mastoid operation within a few days or weeks of the commencement of disease according to the urgency of symptoms and condition of hearing. If, however, the aural surgeon—as some did—held the power of hearing in little estimation, and was content with saving life, then he might allow the discharge to continue until the patient died of old age, or until dangerous symptoms appeared, and then perform a radical mastoid operation.—Dr. Spicer showed a case of new growth on the palate which was thought by the Fellows present to be papillomatous in nature.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in Liverpool on Feb. 20th, Dr. J. H. Willett (Liverpool), the President, being in the chair.—Dr. J. E. Gemmell (Liverpool) showed: 1. A specimen of Carcinoma of Cervix commencing during pregnancy, from an 8-para, aged 34, which had caused hæmorrhage during the later months of pregnancy. Labour was normal, but the hæmorrhage continued, and there was pain referred to the right hip and thigh. On examination the cervix was enlarged, its inner surface being rough and boggy. The uterus was removed by pelvic dissection, the patient making a good recovery. Microscopic section showed a glandular carcinoma. 2. A specimen of Carcinoma of Ovaries removed from a patient aged 41, with a diagnosis of double chronic inflammatory appendages. The growths were adherent to the floor of the pelvis, to omentum and rectum; the left contained pus. Microscopic section showed a mass of glandular carcinoma. Dr. Gemmell also reported a case of Solid Ovarian Tumour as a cause of dystocia necessitating Cæsarean section. The patient was a 2-para, the first confinement being normal. Twelve hours after the commencement of labour her medical man found the head obstructed by a hard swelling which filled the pelvis. This tumour could not be moved so Cæsarean section was performed, and subsequently a solid tumour of the left ovary, the size of a fœtal head, was removed. Convalescence was complicated by a cystic swelling over the sacrum, which eventually had to be opened.—Dr. D. Dougal (Manchester) read the notes of a case of Ectopic Pregnancy occurring twice in the same patient. The patient, a 1-para, aged 28, went two weeks over her period in July, 1912, and was operated upon for a ruptured ectopic pregnancy of the right tube; this tube and ovary were removed. Menstruation was now regular for 14 months, when she again went over her period for two weeks, and was now operated upon for a ruptured ectopic pregnancy of the left tube. Figures were given to illustrate the frequency of this condition.—Mr. W. P. Gowland (Liverpool) gave a demonstration of Born's method of reconstructing embryos in wax. The embryo was first cut in serial sections and the method of drawing these on an enlarged scale by means of the Edinger projection apparatus was demonstrated. The conversion of the drawing on thin tissue paper into a wax plate was also shown and the means to secure accurate orientation when the plates were superimposed to form the complete model. Great stress was laid upon the necessity of proper fixation of the embryo in as fresh a condition as possible. Models of human embryos, kindly lent by Professor Peter Thompson and Mr. N. C. Rutherford, were on view. During his remarks Dr. Gowland pointed out the necessity for a closer association between the gynæcologist and the anatomist, as only by coöperation between the two could many embryological problems be solved.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 6th, Dr. David Ross, the President, being in the chair.—The President showed a man, aged 46, who took to his bed, after being unfit for a week, with symptoms suggesting influenza. Two days later he was seen by Dr. Ross and found to have a temperature of 102° F., general rhonchi, cough, dorsal backache extending to the sternum, which was tender; the tongue was dry and brown; he looked very ill. The pain lasted for six days, then gradually disappeared, and in 17 days from being medically seen the patient thought medical attention unnecessary. A few days later the pain recurred. Dr. Ross was again called in on the nineteenth day from his first visit to find an abscess pointing over the mid-sternum the size of a teaspoon bowl. This was incised and about

300 c c of pus let out The sternum was perforated The man [illegible]

lasting a minute or two He could induce but could not inhibit the spasm Treatment had been ineffectual —Mr W C M Donnell showed a man, aged 31, the subject of old Right Pleurisy, Emphysema, and Chronic Right sided Pulmonary Tuberculosis, whose apex beat was two inches below and half an inch inside the right nipple The liver was on the right —Mr J J Udale showed a man aged 53 with Elephantiasis of the Left Leg of 19 years' standing that commenced after erysipelas of that leg There had been recurrent attacks Filariæ were not present Lymphangioplasty had been twice done with temporary success on the second effort Autogenous vaccine treatment had been tried without benefit —Mr H Curtis advised further careful autogenous vaccine preparation and use —Dr B G Morison read notes of a case of Acute Rheumatism in a girl of 11 years, who had purpura at its commencement followed by endocarditis leaving a damaged mitral valve

LEEDS AND WEST RIDING MEDICO CHIRURGICAL SOCIETY —A pathological meeting of this society was held on Feb 27th at the Leeds School of Medicine, Dr T Wardrop Griffith, the President, being in the chair —Dr A S F Grunbaum read a paper entitled "Theoretical and Experimental Aspects of the Treatment of New Growths" which was discussed by Mr G Constable Hayes, Dr J E Eddison, and Mr J F Dobson —Dr C W Vining showed a specimen from a case of bilateral cortical infarction found post mortem in a girl of 16 dying from general peritonitis following acute intestinal obstruction It was pointed out that this kidney condition was rare, and when it did occur it was in cases of women dying from eclampsia at childbirth —Dr G W Watson showed a Portion of Lung and a Spleen from a case of Phthisis which terminated fatally six to eight weeks after the onset of symptoms The signs in the chest extended very rapidly during the last four weeks of life, and death occurred suddenly from a severe hæmoptysis The spleen showed a massive infarction It was suggested that the cause of this infarction, and also that of multiple small infarctions which were present in the kidneys, was probably detachment of portions of clot from thrombosed pulmonary veins

Reviews and Notices of Books.

Studies in Water Supply

By A C HOUSTON, D Sc, M B, C M Edin London Macmillan and Co, Limited 1913 Pp 203 Price 5s net

IT is frequently asserted, and with considerable ground, that as regards the science of bacteriology, and particularly as regards that portion of it of which practical use is made in medicine, we in this country owe an immense debt to France and Germany All the more credit therefore, is due to Dr Houston in that he has applied bacteriology to the problem of water supply in such systematic, careful, and progressive fashion that the laboratory of the Metropolitan Water Board has become in this matter the pioneer water laboratory of the world

The present monograph contains an account of some of the numerous and important investigations that have been made by Dr Houston and his assistants on problems in relation to water supply, and it has, of course, special reference to the water supply of London We shall not here refer to the general considerations of the work done at the laboratory of the Metropolitan Water Board, as these have already been fully dealt with in a leading article in THE LANCET of Feb 7th, 1914, p. 398, but shall confine ourselves to a consideration of details

The continuous examination of the water of the Thames and Lee has enabled Dr Houston to indicate the times at which from the point of view of quality it is desirable to abstract water for supply, and the times at which abstention is preferable Dr. Houston employs the colour test for this purpose, and uses Burgess's scale for classifying the results

Regarding the preliminary purification of raw water the improvement in quality to be obtained by simple sedimentation is thus clearly shown —In an experiment with a small storage reservoir of 7,000,000 gallons capacity it is noteworthy that a nominal storage of only 15–16 hours produced a percentage reduction in the bacteria of 39 2, in the ammoniacal nitrogen of 20, and in the turbidity of 21 8 Dr Houston finds that the use of coagulants increases this preliminary purification, and he has also a word to say in favour of mechanical or pressure filters which at York, during a trial lasting for three years, appear to have produced the very satisfactory reduction of the bacteria by 85 per cent

It is characteristic of Dr Houston that, although making the fullest use of available methods and sparing no pains to substitute well ascertained and patiently collected facts for the previous vague knowledge, he has always had an eye to the introduction of improved measures of water purification It is clear from the present book that the idea of absolutely freeing a water of all its living germs has been much in his mind No doubt this idea of sterilising a large volume of water arose in connexion with sewage effluents in the course of his previous work as bacteriologist to the Royal Commission on Sewage Disposal For Dr Houston, in the typhoid outbreak of 1905 at Lincoln, which was traced to the water supply, performed the memorable task of sterilising the water supply of the town without interfering with the service We believe that we are correct in stating that this was the first occasion on which such a feat had been accomplished in any country It is necessary to emphasise the point, because Dr Houston's methods were later copied in America where an attempt has been made to present the credit of this pioneer work to an American whose work considerably post dated that of Dr Houston The sterilising agent used by Dr Houston with such success at Lincoln was an alkaline solution of sodium hypochlorite known as "chloros," a preparation which contains from 10–15 per cent of available chlorine, but Dr Houston remarks that bleaching powder, which contains about 33 per cent of available chlorine, is equally suitable The dose of chloros used at Lincoln for sterilising the water supply varied according to circumstances, but was usually 1 100,000, or approximately 1 to 1,000,000 in terms of available chlorine This treatment of the Lincoln water was continued over a period of six years, until a new supply was introduced

Dr Houston has now devised a new and in many ways improved method of sterilising an impure water supply This method he calls the "excess lime method" In the time honoured softening process for hard water a limited dose of lime is added, the amount being carefully calculated so as to be rather less than is needed to combine with the bicarbonates present Dr Houston points out that owing to the purely chemical nature of the object in view this procedure has been so arranged as to prevent the bactericidal action of the lime. By his "excess lime method," therefore, the water is purposely overdosed with lime so as to bring about a known bactericidal effect, and then, after a suitable interval, the water is mixed with enough untreated stored water to combine with the excess of lime. Dr. Houston gives numerous experiments and particulars, from which it appears that the bactericidal dose of lime for hard waters is rather less than 1 to 5000, and for very soft waters more than 1 to 50,000. He points out the circumstances under which the excess lime method is specially attractive and cites the following instances. 1. In the case of a water bacteriologically impure, which in any case it is proposed to soften. 2. In the case of a contaminated river-supply where sand-filtration is the only safeguard, where there is hardly any available storage accommodation, and where the occasional use of flood water is necessary for waterworks purposes. 3. In the case of wells not sufficiently pure to be used without some form of treatment, and concerning which some doubt exists as to whether storage *plus* subsequent filtration would prove an altogether satisfactory remedy. 4. In the case of surface waters unduly "soft" and not free from undesirable pollution. The river Dee, from which the water-supply of Aberdeen is taken, is a case in point, and it may be noted that the result of an experimental trial at Aberdeen of Dr. Houston's process has been so satisfactory that the town council has now decided to use the method continuously.

The particulars which have been given are enough in themselves to show the enormous importance of the work collected in this monograph to those who have to deal with water-supply. The remaining chapters contain a synopsis of the well-known researches of the Metropolitan Water Board laboratory on the purifying effect of storage, and also a full description of the bacteriological methods used there. Two chapters, however, remain that will be of special interest to medical officers of health and to members of public bodies who have to deal with water-supply. Dr. Houston's chapter on Water and Disease is full of information on the subject, and as temperate as illuminating. The comparison between the typhoid death-rates in the principal cities of Europe and in many cities of the United States tends to prove that America is much behind Europe in the prevention of typhoid fever. Dr. Houston's suggestion that comparison should be made of the water-supplies of all these cities both in Europe and America by standard bacteriological methods such as those which are in daily use at the laboratory of the Metropolitan Water Board is one that deserves to be acted upon. For without doubt such an investigation would yield results of great value, not only in the diagnosis and treatment of bad water-supplies, but also in the saving of human life. In addition, this inquiry would assist towards the perfection of that science of a pure water-supply which Dr. Houston himself has done so much to build up.

Flies in Relation to Disease: Non-Bloodsucking Flies.

By G. S. GRAHAM-SMITH, M.D. Cantab. Cambridge: University Press. 1913. Pp. 292. Price 10*s.* 6*d.* net.

THE rôle of flies in communicating disease through protozoan parasites, which undergo stages in their life history within the flies, is so important and has been so much written about that we are apt to forget another and very deleterious function performed by these insects.

The communication of such diseases as malaria is brought about entirely by biting flies; but such flies as well as others which only wander over the human body, especially upon sore places, may also be as deadly in their way, for they often bring with them attached to their mouth parts, or even merely to the walking limbs, germs of various diseases which they have accidentally picked up from filth of various kinds upon which they feed. This mode of infection is so obvious on *a priori* grounds that experimentation and observation are, theoretically speaking, almost unnecessary. But although the presence of danger from possible "myiasis" of this kind seems clear without further discussion, the author is of opinion that "the general tone of the medical profession is apathetic" in the matter. Dr. Graham-Smith sets himself to amend this laxity, and devotes a large part of his book to detailing important experiments which absolutely prove the deadly rôle that is played by many species of flies.

It will astonish even the reader with zoological knowledge to learn what a large number of species of diptera are to be found in the ordinary dwelling house. To most of us the house-fly, an occasional blue-bottle, a gnat or two, would seem to exhaust the dipterous possibilities. But Dr. Graham-Smith enumerates no less than 18 species, and these are only the "common house-frequenting non-biting flies." The relative importance of the different species as germ carriers is considered, a relation which depends largely upon the numbers of each species. There is no doubt from the figures given by Dr. Graham-Smith that Musca domestica is far the commonest, and therefore the most dangerous. The numbers of this fly, as compared with all others, are in some cases from 80 to 90 per cent. of the total fly population of a house. These various flies are treated of in some detail as to their structure and development, as well as their mode of life, the structure being explained by many plates. It is, of course, the habits and life history which have the greatest interest in relation to the question of disease carrying; and a vast number of these insects are known to be dung frequenters, a large proportion again being attracted by human excrement. It is, of course, in this that their danger lies.

But while these facts are of much practical as well as theoretical importance, the author does not leave us with such only partial instruction as to the rôle of flies in conveying infection. It is one thing to assert that flies can transmit the germs of various diseases propagated by germs, and another to prove that they actually do so. Dr. Graham-Smith points out that in the past epidemics of flies were believed to be associated with disease epidemics. Sydenham, for example, associated the prevalence of flies in summer with a sickly autumn. But a more definite and positive association between non-biting flies and the transmission of disease is new, and dates only from late in the last century. An immense amount of information, partly gathered by himself, is brought forward by Dr. Graham-Smith concerning actual experimentation with flies; the discovery upon them of many pathogenic organisms and the length of time which these organisms can live upon their temporary and accidental hosts are considered. Many of these experiments might be cited, but we shall call attention only to the author's researches upon B. [illegible] ich are elaborately tabulated. Th[illegible] that the bacterial organism could live in the fly's crop for four or five days and sometimes even longer, and it was proved that cultural plates could be infected by flies which had taken up these bacteria.

The volume ends with a very copious bibliography, zoological as well as pathological. Of the very greatest use as a compendium of the subject from the sanitary side, Dr. Graham-Smith's work may be commended as a useful addition to zoological literature.

Spezielle Pathologie und Therapie Innerer Krankheiten.

Edited by FRIEDRICH KRAUS and THEODOR BRUGSCH. Lieferungen 1-4 (Bd. I., Halfte I., pp 1-238); Lieferungen 5-8 (Bd. II., Halfte I., pp. 1-240); Lieferungen 9-12 (Bd. II., Heft 2. pp 1-259); Lieferungen 12-16 (Bd. II., Heft 1, pp. 241-430) Berlin und Wien: Urban und Schwarzenberg. 1913. Price 2 marks, or 2.40 kronen each Lieferung.

THE aim of this new work, according to a prefatory note, is to sum up the present state of medical knowledge. The editors point out that nowadays knowledge is so rapidly increasing that our ideas concerning disease are frequently changing, and so at certain intervals it is as well to take stock.

The work is not intended to be an encyclopædia, such as that of Ziemssen or Nothnagel. It consists of a series of monographs by writers who have made a special study of their subject, and is to form a succinct and critical survey of medical science at the present day. It is written especially for the practising physician, and consequently much attention has been directed towards the clinical and therapeutical aspects. Judging from the list of distinguished contributors and the scheme of work as laid down in the prospectus, it is evident that the editors have done their work of selection well, and we may say at once that if the succeeding parts maintain the standard of these, the work will be thoroughly valuable.

The first part deals with diseases of metabolism. Professor Magnus-Levy, of Berlin, writes on gout and diabetes mellitus, including lævulosuria, heptosuria, glycosuric acid excretion, and glycosurias of non-diabetic nature. He illuminates the subject of chemical pathology, and gives illustrative cases from his own clinic, showing how carefully and in how detailed a manner such cases are investigated, and appends instructive charts of the daily nitrogenous excretion. Though gout and diabetes are here described as separate entities, Professor Magnus-Levy discusses the relations of gout to diabetes and to obesity, and thus the idea is fostered that these are by no means independent diseases, and this is further elaborated in the section by Professor Fr. Umber, of Berlin, on the intermediate disturbances of metabolism. Under the heading of amino-acid diathesis he discusses cystinuria, diaminuria, and alkaptonuria, and takes the reader step by step through the disintegrative process therein concerned. In the same section are dealt with, diabetes insipidus and cachexia.

The second, third, and fourth instalments contain the greater part of the section devoted to infective diseases. The first 148 pages are taken up with a general review of the phenomena of infection and immunity, by Professor R. Kraus, of Buenos Aires; in this section are included such subjects as the meiostagmin reaction and Abderhalden's tests for carcino [illegible] gens writes [illegible] out that th [illegible] tigation do not as yet account for all the features of the epidemic conditions. He insists on the septicæmic character of typhoid fever as opposed to the old view of its local incidence on the intestinal glands, and advises early resumption of solid food in the form of biscuits and the like, instead of keeping the convalescent patient for a long time on slops. Professor Jürgens also treats of dysentery and of influenza. He holds that the former is a true specific disease due to the Kruse-Shiga bacillus, amœbic enteritis being a separate affection often combined with dysentery. The causal connexion of influenza with Pfeiffer's bacillus he regards as not proved, as the organism is apparently absent in many epidemics. Diphtheria is described by Professor F. Meyer, who notes that there are many gaps in our knowledge of the etiology, nature, and treatment of this disease, among which is the doubt as to the relationship between the Klebs-Loeffler and the pseudo-diphtheria bacilli. The section on tetanus is by Dr. R. Ritter von Stenitzer, and that on epidemic cerebro-spinal meningitis by Professor W. Knöpfelmacher, while Professor W. Weintraud writes on acute rheumatism. The last named writer does not regard any of the different micro-organisms described as present in cases of rheumatic fever as the proved cause of the malady, nor does he look on salicylates as true specific remedies in the sense of attacking the causal agent: they are merely convenient antipyretics which can be given in larger doses than others, such as the coal-tar derivatives, which are more immediately toxic. Finally, Professor E. Peiper contributes an article headed indigenous helminthiases, in which are included, curiously enough, accounts of certain ciliate protozoa (balantidium and lamblia), pediculi, sarcoptes, and so forth.

There are numerous illustrations throughout the various parts, many being coloured plates, which are well done. The plan and execution of the articles are alike excellent; there is a copious bibliography to most of the sections, and the whole forms a first-class text-book and a valuable work of reference in the subjects with which it deals.

Science and Education.

A Series of Volumes for the Promotion of Scientific Research [illegible] -d by J. MCKEEN CATTELL. [illegible] *Education.* New York and

THIS book is a collection of 28 addresses delivered and papers read on various occasions by American medical men eminent in their respective departments. The papers are not all recent; they bear various dates, indeed, from 1899 to 1912, and all but two have been previously published in some medical or scientific journal or other. But a common aim runs through them all, in that all deal with some aspect of the relations between research or education, or both, and medicine. It is impossible to do more than enumerate them here. Professor Richard M. Pearce, of the University of Pennsylvania, opens the volume with the Hitchcock lectures for 1912 at the University of California on Research in Medicine. They are five in number, and treat respectively of the historical aspect of the subject down to the nineteenth century, the influence of physics and chemistry, the rise of bacteriology, present-day methods and problems, and the position of medical research in America. Other papers are: The Experimental Method, and Chance and the Prepared Mind, also by Professor Pearce; the Interdependence of Medicine and other Sciences of Nature, Medicine and the University, and the Relation of the Hospital to Medical Education and Research, by Professor W. H. Welch; the Medical School as part of the University, by Professor W. H. Howell; Liberty in Medical Education, by Professor Franklin Mall; Medicine and the Universities, and Some Tendencies in Medical Education in the United States, by Professor L. F. Barker; Certain Ideals of Medical Education, by Professor C. S. Minot; the Career of the Investigator, by Professor W. B. Cannon; Some Experiences of a Medical Teacher, by Professor W. Councilman; the Place of Medical Research in the University Medical School, by Professor Theobald Smith; two addresses not hitherto published, respectively on the Outlook in Medicine and Problems, Methods, and Organisation of Research, with Special Reference to Physiology, by Professor G. N. Stewart; the Improvement of Medical Teaching, by Professor C. M. Jackson; the Equipment and Instruction of the Laboratory Years, by Professor E. P. Lyon; the Educational Function of Hospitals and the Hospital Year, by Professor James B. Herrick; the Addition of a Fifth Year to the Medical Curriculum, by Professor J. M. Dodson; Medicine and Sociology, by Professor C. R. Bardeen; the Relation of Research to Teaching in Medical Schools, by Professor W. Ophüls; the Science of Clinical Medicine, What it Ought to be and the Men to Uphold it, by Dr. S. J. Meltzer; the Public and the Medical Profession, by Professor James Ewing; the Duties and Responsibilities of Trustees of Public Medical Institutions, by Professor W. W. Keen; Research Foundations in their Relation to Medicine, by Dr. Henry H. Donaldson; Imagination and Idealism in the Medical Sciences, by the late Professor Christian Herter; and the Medical School of the Future, by the late Professor H. P. Bowditch. The subjects are for the most admirably handled, and in an interesting manner, though naturally many of them are of a debatable nature. While many of the papers deal with problems peculiar to the United States, others constitute a discussion on first principles that should have great interest for all concerned with medical education and research.

Food and Feeding in Health and Disease: A Manual of Practical Dietetics.

By CHALMERS WATSON, M.D. Edin., F.R.C.P. Edin. Second edition, revised. Edinburgh and London: Oliver and Boyd. 1913. Pp. 638. Price 10*s.* 6*d.* net.

THIS book is a very serviceable one owing to its practical character. Whilst rendering a clear account of the principles of dietetics, a very large section is devoted to the actual preparation of foods.

There are altogether 32 chapters, ten of which deal with preliminary considerations, as, for example, the function of food, its chemistry and physiology, digestion, absorption, the rôle of bacteria, the composition of animal and vegetable foods, beverages, preservatives, and adulteration. The section on diet and the choice of foods commences at Chapter XI., which relates to diet at different periods of life. Subsequent chapters give excellent practical directions as to the adaptability of foods in disease.

The author's views on the articles of diet that may be allowed in glycosuria and diabetes are of interest. In regard to carbohydrates he says that as a matter of practical experience in the treatment of diabetes the complete deprivation of starch in the breadstuffs is found to be so great a trial and becomes so irksome that it is usually necessary, and often desirable, to allow a small amount of ordinary bread. We find no reference to those foods which, although containing a large proportion of starch, claim to be suitable for diabetic patients on the ground that the starch has been so modified as to be easily digestible, the amount of sugar in the urine not being increased by their careful use. The book is full of sound observations on these and cognate matters. In the somewhat extensive appendix are published the results of the experimental researches carried out by the author and others in collaboration in the physiological laboratory of Edinburgh University since 1900. Some of these papers have appeared in our columns.

In the preface to the first edition the author acknowledges that in the preparation of the work he has derived much help (more especially with the data of the chemical composition of foods) from many sources, special mention being made of the writings of Atwater, Langworthy, "and of the analytical reports published from THE LANCET Laboratory." *We much appreciate the terms of* this acknowledgment.

Diseases of the Skin.

By HENRY W. STELWAGON, M.D., Ph.D., Professor of Dermatology in the Jefferson Medical College, Philadelphia. Seventh edition, thoroughly revised. Illustrated. London and Philadelphia: W. B. Saunders Company. Pp. 1250. Price 25*s.* net.

Dr. Stelwagon's work requires no introduction to English readers, and the fact that the seventh edition has appeared so shortly after the last speaks for the usefulness of the volume.

Considerable alterations and additions have been made. The book weighs nearly six ounces heavier than it did in the fifth edition, but the print is clearer and less trying to the eyes than in the earlier editions. The illustrations, to which 40 have been added, have a high standard of lifelike representation throughout. Descriptions have been added of prurigo nodularis, granuloma pyogenicum, benign sarcoid, and keratosis blennorrhagica. The footnote references are a valuable feature of this book—we note that there is over a page of references given under pellagra, the latest of these being that of Sambon, 1912. Dr. Stelwagon still gives details of X ray exposures by noting the spark gap, but the pastille measurement is also required to convey any accurate meaning to another worker with different apparatus.

We can heartily recommend this book for advanced students and practitioners.

Die Sanitätsausrüstung des Heeres im Kriege.

Mit Genehmigung des König. Preussischen Kriegsministeriums unter Benutzung amtlicher Quellen. Bearbeitet von Dr. W. NIEHUES, Oberstabsarzt im Kriegsministerium. Mit 239 Abbildungen auf 73 Tafeln und im Text. Berlin: August Hirschwald. 1913. Pp. 527. Price 24 marks.

DURING the last 20 years a large number of works on military surgery have been published under the direction of the Medical Department of the Prussian War Office. These have dealt with many urgent questions which concern the medical section of an army, but the present volume is as important as any of those which have preceded it. It deals with the equipment of the medical section of an army in time of war. It commences with a *description of* the field dressing, of which every soldier carries two; on the dressing are printed full directions for its immediate application to a wound, and the dressing is so arranged that it may be applied without being touched by the fingers.

An interesting description is given of the portable bacteriological laboratory; it includes a very complete set of apparatus for bacteriological work. The portable dental equipment is also very complete, and includes the appliances necessary for fillings. Then follows a description of the wagons in which are carried the medical fittings, and also of the wagons for the transport of the wounded. The account of the surgical instruments provided and the way in which they are carried is detailed, and the hospital tents are described. Of great interest is the account given of the railway carriages fitted for the conveyance of the wounded and of the apparatus for the Röntgen rays.

This work shows to what a high degree of efficiency the Prussian army has carried its medical equipment, and the great attention paid to detail.

LIBRARY TABLE.

Child Labour in the United Kingdom. By FREDERICK KEELING, M.A. London: P. S. King and Son. 1914. Pp. 326. Price 7s. 6*d*. net.—The medical profession has a special interest in any question that tends to influence for good or evil the physical and mental welfare of the race. This is a study of the development and administration of the law relating to the employment of children in the United Kingdom. After an introduction in which the history and present position of child labour legislation is described the book is divided into six parts. Part I. traces the development of child labour regulations (outside of factories, workshops, and mines) in the United Kingdom. Part II. discusses the administration of child labour regulations, including a summary of recommendations. Part III. gives tabular analyses of local by-laws. Part IV. consists of reports, notes, and tables relating to the action of local authorities in enforcing child labour regulations. Part V. contains the principal Acts regulating the employment of children. Part VI. gives chronological lists of the Acts of Parliament and Orders, and British Government reports and other official documents, with separate indexes for the volume, to places, persons, and subjects. The work is full of well-digested information.

A Manual of X Ray Technic. By ARTHUR C. CHRISTIE, Captain, Medical Corps, U.S. Army. London and Philadelphia: J. B. Lippincott Company. 1913. Pp. 104. Price 6s. net.—This is a manual describing the construction, operation, and use of the various forms of apparatus used in X ray work. It is of a purely electro-technical character, and in no sense a medical work, except in so far as the apparatus is employed for medical investigation. Most forms of apparatus are explained and illustrated, diagrams being freely employed where necessary. It will be found useful for those who are taking up radiology and wish to make themselves familiar with the intricacies of the instruments they will have to use. The idea of a technical book describing and explaining the numerous electrical and other technical apparatus used in medical work is a good one. Such a book might be made even more comprehensive than the one here reviewed; it would do much to render unnecessary the tedious initial chapters of nearly every book that appears on medical electricity and radiology.

Ambidexterity and Mental Culture. By H. MACNAUGHTON JONES, M.D.Q.U.I., M.A.O.R.U.I. (Hon. Cau.), F.R.C.S. Irel. & Edin. London: William Heinemann. 1914. Pp. 102. Price 2s. 6*d*. net.—The subject of right- and left-handedness and ambidexterity crops up at intervals and leads to considerable argument. In this book Dr. Macnaughton Jones presents the case in favour of a training in ambidexterity from earliest infancy, and considers the objections that have been urged against it. He gives several reproductions of left-handed drawing and writing, and of simultaneous two-handed writing, two of which are very remarkable. First the writing of a girl of 16 with her left hand and right hand simultaneously, in which it would be difficult to distinguish either writing from the other apart, and secondly the right- and left-handed signatures of Sir Robert Baden-Powell, of which the same remark may be made. Occasional instances, however, are hardly likely to outweigh the effect of such experiments as those made in the Berlin Public Schools by Dr. Dickhof, to which reference was made in an annotation on Left-handedness Among School Children in THE LANCET of Feb. 21st.

JOURNALS AND MAGAZINES.

The American Journal of Tropical Diseases and Preventive Medicine. Vol. I., No. 7.—The January issue gives a report by Dr. J. A. Chatard and Dr. C. G. Guthrie on a carefully observed case of Human Trypanosomiasis occurring in Baltimore. The disease, however, was contracted in Africa, and the patient had remained free from symptoms for over three years after 19 weeks' treatment there. In this relapse the improvement after a single dose of salvarsan was striking. As to purely mechanical transmission by mosquitoes or other biting insects, this is held to be negligible, for it would involve interrupted feeding and immediate passage of the insect from the patient to an uninfected person. Dr. J. Allan McLaughlin discusses the influence of water-borne disease on the mortality of children, and points a warning finger to the fact that so-called water-borne diseases are transmitted also by other agencies, such as milk, flies, and dirty fingers. He urges the importance of sound sanitary teaching on these matters in the schools, and points to the success of this method in the Philippines, where the school-taught children instructed their parents with greater success than could be achieved by any health officer. Dr. Bayard Holmes, in a paper on the Outlook for Dementia Præcox, champions Abderhalden's defensive ferment reaction as a means of objectively diagnosing dementia præcox, and finds a gleam of hope in the reports of Lundvall and Donath, who have reported cures of 30 per cent. by protracted artificial hyperleucocytosis. Dr. Allan Eustis reports a case of long-standing amœbic abscess of liver and lung cured by intramuscular injection of emetine hydrochloride.

Orthopédie et Tuberculose Chirurgicale. Paris: J. B. Baillière et Fils. Subscription abroad 18 francs. Separate numbers (two-monthly) 3 francs each.—Under this title the first number of a new French journal has recently appeared, with Dr. Ménard as director, Dr. Calvé and Dr. Lamy as editors, and with a long list of collaborators, representing England, Germany, America, Austria, Belgium, Spain, Holland, Italy, Portugal, Russia, Sweden, and Switzerland. The international character is well shown in this first number, which contains an important article upon spinal caries, by V. Ménard; an account of the progress in tendon transplantation, by F. Lange; the treatment of scoliosis, by R. W. Lovett and by Mackenzie Forbes; an account of the hospital and college at Alton, by H. J. Gauvain, as well as other articles and a review of orthopædic literature. The journal is of good size, well printed and illustrated, and if the standard of the first number is maintained it will prove a valuable addition to orthopædic literature.

The Dental Cosmos. Philadelphia: The S. S. White Dental Manufacturing Company. Price 20c.—In the February issue Dr. W. J. Gies contributes a paper of considerable value on the Relation of Sulphocyanite to

Dental Caries. In the summary of general conclusions he remarks "that there is nothing about the known quantities of sulphocyanite to indicate that it is able, in the proportion of its normal occurrence in saliva, to affect the secretory tendencies of the salivary or buccal glands, to modify the oral membranes, to influence the teeth from any standpoint, or to stimulate or retard or alter the activities of the oral micro-organisms." Dr. George Brown, in a paper on Upper Maxillary Contraction and Expansion, states that he has seen marked improvement in the general health follow the spreading of the upper arch. There are several skiagrams of cases given, but the paper is by no means convincing. In the discussion on the paper Dr. Stanton records an experiment on a post-mortem specimen. With the aid of a powerful spreading appliance he was able to spread the molar teeth, but he was not able to open the intermaxillary suture. On removing the appliance the teeth promptly returned to their original position.

Journal of Micrology and Natural History Mirror. Reading: 22, Carnarvon-road. Price 4*d.* monthly. Pp. 20.—This journal will be of interest to those who use the microscope to any extent for recreation. This, the first, issue contains, among other interesting features, an article on a simple camera for photomicrography, a lesson in tracing the genealogy of an unknown organism, a note on large- *versus* small-tubed microscopes, pond-life notes, the description of a quickly prepared slide of bacteria, and the commencement of a series of articles on mounting objects. It is an excellent publication for the amateur, and the character of the articles is indicated by an extract from the editor's opening remarks: "For the aid of those whose enthusiasm is deeper than their pockets we shall preach the gospel of 'paste board and string,' of the 'soldering bolt and the unconsidered waste trifle.'"

# Reports and Analytical Records
FROM
THE LANCET LABORATORY.

BYNO-CHRISMOL.
(ALLEN AND HANBURYS, LIMITED, 37, LOMBARD-STREET, LONDON, E.C.)

IT is remarkable how satisfactorily liquid paraffin blends with an active malt extract. Byno-chrismol, for example, which contains equal quantities of chrismol, a specially prepared liquid paraffin, and active malt extract, bynin, may be described as a very nearly clear fluid, so intimately is the oil bound up with the malt extract. As a matter of fact, the preparation is opalescent and shows complete uniformity of composition. Examined under the microscope it appears perfectly homogeneous and free from oily particles. The addition of water instantly produces a uniform emulsion. We find that the preparation exhibits a marked digestive activity on starch, and the quantity of oil incorporated is in accordance with the claim. The moisture amounted to 17·13 per cent., mineral matter to 1·07 per cent., and the malt sugar to 32·00 per cent.

KEROL CAPSULES.
(QUIBELL BROTHERS, LIMITED, NEWARK.)

The efficiency of kerol as an antiseptic and disinfectant is attributed to the fact that it contains a di-phenyl nucleus instead of a mono-phenyl nucleus, as is the case with carbolic acid. Apart, however, from the application of kerol in general sanitary or medical practice, it has received considerable praise as an intestinal disinfectant. For this purpose it is administered in capsules which secure its conveyance to the intestinal tract. Clinical observations show that it possesses distinct advantages for this purpose compared with the similar employment of salol, beta-naphthol, and other well-known intestinal antiseptics. An interesting series of cases is reported in which its value in intestinal flatulence and alimentary toxæmia is reported. Kerol was examined by THE LANCET Commission on Disinfectants in 1909 and the results awarded it a high carbolic acid coefficient. Professor Hewlett reports kerol to be 60 times less toxic than phenyl when compared with quantities of equal germicidal efficiency. This statement is most important in regard to the clinical applications of this antifermentative and germicide.

CARNINE LEFRANCQ.
(WILCOX, JOZEAU AND CO., 49, HAYMARKET, LONDON, S.W.)

Our analysis of this preparation confirmed that published by the Municipal Laboratory of Paris, although this latter analysis does not differentiate the albuminous principles. The feature of the preparation is that it contains the fresh juice of muscle expressed by pressure at a low temperature. It should, therefore, contain coagulable albumin, which we found to be the case. The amount coagulated by boiling proved to be 3·22 per cent., while the total albuminoids present was 5·68 per cent. The juice is preserved in syrup and glycerine, which render the addition of other antiseptics unnecessary. The method of preparation is of clinical importance, since not only is muscle albumin present in easily assimilable form, but it contains also the active enzymes of the muscle plasma. Uncoagulated meat juice gives the hæmoglobin spectrum, and this is the case with carnine Lefrancq.

IRISH WHISKY.
(DUNVILLE AND CO., BELFAST. LONDON: 239 AND 241, SHAFTESBURY-AVENUE, W.C.)

An analysis of two specimens of whisky from this firm appeared in our issue of Feb. 8th, 1908, and as showing the constancy of composition these analyses have been repeated on samples recently sent to us. The secondary products in V.R. brand were as follows, given in parts per 100,000 of alcohol present: Ethers, 31; aldehydes, 5·4; higher alcohols, 109; and furfural, 0·32. These figures are in substantial agreement with those previously published. With regard to the special liqueur, the recent example examined showed a reduction in the amount of furfural and higher alcohols, but in other respects the chemical composition of the liqueur remains the same. Both specimens evidenced maturity and possess that peculiar flavour characteristic of genuine Irish whisky. The standard quality of these whiskies is evidently maintained.

GRANULATED KOLA GLYCEROPHOSPHATES.
(A. WANDER, LIMITED, 1 AND 3, LEONARD-STREET, FINSBURY, LONDON, E.C.)

The appearance of this preparation is that of small sections of vermicelli, except that it is of a light chocolate colour. It affords an attractive method of administering the glycerophosphates coupled with fluid extract of kola-nut, which possesses marked stimulating properties. The dose is from one to two dessert-spoonfuls given with each principal meal. We confirmed the presence of both calcium glycerophosphate and caffeine, to which may principally be ascribed the stimulating properties of kola-nut. In one ounce of the granulated preparation we found ½ grain of caffeine and 8 grains of glycerophosphate of calcium. The medicinal value of these constituents is well known, and the preparation affords a pleasing way of administering them.

LETTERS TO MEDICAL MEN

5. THE PHYLACOGEN TREATMENT OF SCIATICA.

NOTE.—The medical reports quoted in this letter are published by permission. On request, we shall be glad to place any *bonâ fide* enquirer in communication with the authors.

Sciatica a Symptom.

DEAR SIR,—As you are aware, the term "sciatica" has rather a wide connotation, being applied to various painful affections of the sciatic nerve. These are mainly inflammatory and perineuritic, since it is the neurilemma that is usually involved. The condition is frequently only a symptom, and until the actual source of the pain is understood, is often exceedingly intractable; hence the necessity for that accurate diagnosis which we have already insisted upon in these letters.

Sciatica may arise from inflammation (acute or chronic) of the neurilemma, the result of cold, gout, rheumatism, gonorrhœa, syphilis, or one of a variety of toxic agents; or from pressure, from whatever cause arising, directly upon the nerve, its various branches, or upon the lumbar plexus.

Rheumatism a frequent cause.

According to a writer in "Modern Treatment" (vol. ii, page 573), "rheumatism is the most frequent cause" of sciatica. In the absence of a positive diagnosis it seems reasonable, therefore, to assume that Rheumatism Phylacogen is indicated in the majority of cases.

We have records of upwards of 50 cases of sciatica that have been treated with Rheumatism Phylacogen, and of these 89 per cent. were cured. Of eleven cases reported in this country during the past year a cure was obtained in every instance, and in some of these many months have elapsed since treatment with no return of pain. The following brief clinical reports are specimens of such as we are receiving from different parts of the country:—

A West London Case.

A West London physician reports a case of sciatica which had been under observation for two years. The patient, a male, aged 24, had an attack of sciatica with every change of weather, and he had been treated at various watering places, &c., without result. He had an attack in September, 1912, when he was confined to bed. The sciatica failed to yield to any treatment, and no relief could be obtained. Treatment by Rheumatism Phylacogen was adopted, and after an initial dose of 5 c.c., five doses of 10 c.c. each were injected. Considerable reactions followed. The patient was cured and there was no recurrence of pain.

A North London Case.

The following case was reported from North London:—The patient, a female, 53 years of age, had suffered from sciatica for two and a half years. Salicylates, iodide, and all ordinary remedies and routine treatment had been tried without success. Phylacogen treatment was begun on July 8th, 1913, when 2 c.c. of Rheumatism Phylacogen were injected. July 9th, no change, 3 c.c. injected; 10th, considerable reaction, pain less; 11th, pain decidedly better, 4 c.c.; 13th, pain better, leg still weak, 5 c.c.; 17th, sciatica better, 6 c.c.; 19th, decidedly better, 7 c.c.; 21st, considerable reaction, 8 c.c.; 23rd, very much better, 9 c.c.; 25th, 10 c.c.; 26th, greatly improved, patient walks easily. The patient went back to her occupation, and there was no return of the pain some months later.

A Case from Scotland.

The following report comes from a Scottish Hospital:—When the patient, a young woman, came under Phylacogen treatment she had been suffering from an attack of sciatica of three or four weeks' duration. There was tenderness at all the nodal points of the left sciatic nerve, and some fibrosis of the left thigh and leg. Ordinary remedies had failed to produce any amelioration of the symptoms. The first two doses (2 c.c. and 3 c.c.) gave rise to no reaction, and had little, if any, effect on the pain; but the third injection, 5 c.c., was followed by a sharp rise of temperature and pulse, accompanied by intense pain, and swelling of the left arm and shoulder, which persisted for a couple of days. The sciatic pain, however, had completely gone. The patient remained under observation for three weeks longer, during which time she had no return of the pain and was able to walk and run without any difficulty.

Another Scottish practitioner reports a case of sciatica of six months' duration which improved from the first injection, and which was completely cured; and we have similar reports from Ireland and the South of England.

Dosage of Phylacogen.

The Phylacogens are issued in 10 c.c. phials only. When a dose is withdrawn the rubber cork is replaced, and the liquid keeps perfectly till it is again required. Phylacogen is preserved with a sufficient quantity of phenol to inhibit bacterial growth, and complete sterility is thus ensured. The advantage of the phial package is that any dose, however small, can be given without waste. Beginning the treatment with 1 c.c. doses (which is now recommended) and gradually working up, five or even more doses may be obtained from one 10 c.c. phial.

Our book, "The Treatment of Rheumatic Infections," gives particulars of a considerable number of cases of sciatica treated with Rheumatism Phylacogen, and we shall gladly send you a copy on request.

Yours respectfully,
PARKE, DAVIS & Co.

50, Beak Street, Regent Street, London, W.

A CASE OF

GONORRHŒAL FOLLICULAR URETHRITIS.

Treated by COLLOIDAL IODINE.

BY MARCEL DESCHAMPS,
LATE HOUSE PHYSICIAN, ASSISTANT TO DR BAZY, OF THE "HÔPITAL BEAUJON"; AND
JEAN PERIGAULT,
LATE HOUSE PHYSICIAN OF THE INFIRMERIE CENTRALE DES PRISONS.

THE spread of the gonococcal infection to the follicles of the urethra produces lesions the refractoriness of which is often the despair both of the patient and of the medical attendant; the relatively rapid cure of a case of suppurating and fistulous folliculitis which we have achieved by means of simple medical treatment seems to justify our publishing the following :—

The patient, aged twenty, presented himself at the special department for the treatment of urinary diseases of the Beaujon Hospital on the 20th November, 1913. This patient had been suffering from gonorrhœa since the 20th of October, and had treated himself without success with potassium permanganate irrigations.

On the lower surface of the penis and in its middle portion there was a hard tumour as thick as a nut. This tumour was only painful during erection. The urethral discharge showed abundant gonococci.

We at once submitted our patient to a course of Nicholle's anti-gonococcal vaccine, of which he received a daily injection according to the rules laid down by the author, the treatment being kept up for eleven days.

This treatment exerted no influence either on the discharge (which in no way diminished in intensity) nor on the folliculitis, which progressed in the ordinary manner towards suppuration and culminated in discharging by several small apertures on the 26th of November a sero-purulent fluid which, when examined microscopically, proved to contain gonococci. During the days that followed no change whatever could be found in the urethral discharge; the folliculitis underwent softening, discharging very slowly its sero-purulent fluid. At the same time, a track of lymphangitis appeared on the right side of the penis, an indurated strand being noticed on palpation; the patient was in fact, whilst undergoing treatment, passing through an attack of lymphangitis of the main lymphatics.

On the 30th of November the glandular and lymphatic induration had increased; the temperature had reached 38° C. On the 3rd of December the condition had remained stationary, and the patient was treated by means of extensive irrigation with oxy-cyanide. Though continued up to the 22nd of December, these irrigations did not succeed in drying up the discharge, which had become an obstinate gleet. The folliculitis remained the size of a hazel-nut, hard, and always discharging sero-purulent fluid through the fistulæ; it remained in this condition without any change of consistence, and manifested all signs of chronicity.

We then commenced treatment by means of Colloidal Iodine, injecting it into the anterior part of the urethra to the level of the folliculitis. On the 3rd of January, though the folliculitis did not appear to have been influenced, the discharge had considerably diminished. From this time onward the illness distinctly took a turn towards cure, and the folliculitis commenced to ameliorate, whilst the discharge dried up and the fistulæ closed spontaneously.

On the 15th of January the folliculitis had completely disappeared; seventeen days after commencing the Colloidal Iodine treatment no trace of induration remained; palpation of the urethra on a Benique showed that the canal was absolutely supple, and showed no trace of follicular abscess. **Complete absorption had taken place without the least trace of cicatricial tissue.**

We employed a preparation of Colloidal Iodine obtained by electro-chemical means, and rendered stable by a carbohydrate (Iodargol). Our preparation gave a titre of 20 cg. of Colloidal Iodine to the cubic centimetre. The injection of this product never was in the least painful; it has besides been possible to demonstrate in other cases of gonorrhœa treated by the same method that the pain on micturition disappeared in the course of the acute stage, and the latter is also shortened considerably by injections of Colloidal Iodine.

We have administered doses up to from 2-5 cc. without any bad effects either local or general being produced. It is, in fact, known that iodine when brought into the colloidal state increases its action tenfold and diminishes in toxicity to the same amount.

Nevertheless, we have been satisfied in keeping to doses of 2 cc. (i.e., 40 cg., 6 grs., of Colloidal Iodine), since the higher doses do not seem to us to produce any greater therapeutic effects. The injection was retained by the patient for two hours by means of a constricting dressing which prevented the fluid from escaping.

It has seemed to us of some interest to report this case on account of the result obtained, and above all on account of the means employed for attaining it; for follicular abscesses of gonorrhœal origin, however they may start, always sooner or later acquire chronic symptoms, and we have never so far seen any but surgical treatment leading to a certain cure.

The disinfection and incision of the abscesses from the urethral side, massage after Benique's method, have never led to complete absorption of the lesions. Whenever one has tried to treat the folliculitis in its initial stage, before it has passed on to softening, it should be removed in as aseptic a manner as possible without being opened; if it has suppurated the pocket should be freely opened and disinfected; if it has assumed a cystic appearance, after cooling, it should still be removed surgically. Such is the regular course taken by all experienced practitioners.

The success which has attended our urethral dressings with Colloidal Iodine seems to give some promise that the necessity for the radical methods of surgical treatment we have above enumerated in cases of urethral folliculitis of gonorrhœal origin may be somewhat reduced.

REVUE DE THERAPEUTIQUE MEDICO-CHIRURGICALE,
15th February, 1914.

COLLOIDAL IODINE IN GYNÆCOLOGY.

What is an Ovule?—In gynæcological practice Ovules are regarded with great favour. These products, consisting of solidified glycerine in which some medicament has been incorporated, possess the advantage that such substances can be kept in contact with the diseased part for several hours The selection of the medical substance to be incorporated is therefore of great importance.

Iodine could not be employed.—The most efficacious of active substances, iodine, could never be used in Ovules until we had completed our researches. The reason was that metalloidal iodine rapidly decomposed the glycerine and formed with it an irritant mixture which was absolutely unsuitable for therapeutic purposes.

We have realised this possibility.—Converted into a colloidal state and rendered stable by a carbohydrate iodine may be incorporated with glycerine, without any change taking place in it even *after a period* of several years. (We have samples of Ovules which are absolutely pure after two years.)

Therapeutic value of the Ovules of Colloidal Iodine.—Our Ovules contain 1·50 grm. (22 grs.) of Colloidal Iodine and possess a far higher antiseptic value than the old-time ovules containing 0·50 grm. (7 grs.) of the active substance to the unite volume.

This high dosage of iodine, which is due to the latter being in the colloidal state, far from producing any irritant action, enables our Ovules:

To lessen the pain, rapidly reduce congestion ...... and, further, gives to them considerable cicatrising power.

THE LANCET.

LONDON: SATURDAY, MARCH 14, 1914.

Legislation for Inebriates.

THE report of the inspector under the Inebriates Act for the year 1912 differs from its recent predecessors in being not merely a record of work during the particular period to which the report nominally refers, but rather a general survey of the whole question of the legal control and treatment of habitual drunkards. As Dr. R. W. BRANTHWAITE points out in his introductory letter, such a review of the problem is peculiarly opportune at the present moment, when further proposals are being brought forward to strengthen and extend the application of the principle of restraint as a curative method in dealing with the inebriate; and in the discussion of these proposals the concise account of previous legislative experiments given in the inspector's report should prove useful and convenient.

Dr. BRANTHWAITE very rightly lays much stress on the importance of following the guidance of science in framing practical measures for the treatment of the inebriate; and with this consideration in view he devotes the first part of his report to a statement of the theoretical conceptions regarding inebriety which, in his opinion, are most generally accepted by those who take a scientific interest in this question. In substance, his view is that the inebriate—a term which he uses as synonymous with habitual drunkard, chronic alcoholic, or dipsomaniac—is an abnormal being, "the victim of a psycho-neurotic fault that implies a defective power of resistance to the action of alcohol or drugs, in exactly the same sense as tubercular tendency implies impaired resistance to the specific infection of that disease." We need not stop to consider how far the parallel which this quotation suggests between intolerance of alcohol and susceptibility to microbic infection may be open to criticism; it is sufficient to note that the criterion of inebriety adopted by Dr. BRANTHWAITE is a psycho-neurotic peculiarity shown in the tendency to react abnormally to alcohol. As a similar tendency, however, is met with in most conditions of nervous instability, and as there is no adequate clinical evidence to show that, when observed in drunkards, it presents any special characteristics, or that it ever occurs in such patients without other indications of defect or deviation, it is difficult to see any reason for regarding this sort of inebriety as anything more than a symptom of mental deficiency. No one will be disposed to question this conclusion so far as it applies to a certain category of inebriates, and more particularly to the large majority of individuals committed to reformatory detention under the Inebriates Act of 1898. But it would be an obvious fallacy, and a fallacy pregnant with very serious consequences in practice, if it were to be assumed that this narrow definition of inebriety covers all the cases of alcoholic intemperance which come within the purview of medicine and for which there is need of a State system of institutional care. As a matter of fact, pathological drunkards of this special type are relatively few in number, compared with the more normally constituted individuals in whom intemperance has developed as a result of environmental conditions; and, moreover, it is to these latter cases of environmental alcoholism that institutional treatment can be applied with most prospect of real and permanent effect. It is the more necessary to bear this fact in mind because there is at present an undoubted tendency to adopt the view that inebriety, the inebriety which has been made the subject of special legislation, is essentially an expression of an adherent defect in mechanism. There is always a temptation to apply to bio-social problems the easy hypothesis of a specific innate tendency and to explain crime, or inebriety, or prostitution, by a criminal, or an inebriate, or a libidinous, diathesis; and in the case of inebriety this spirit of *a priori* speculation has been so strong that it has moulded the character and influenced the administration of the legislative measures designed to deal with the habitual drunkard. As a result, the operation of the Act of 1898 has been almost entirely confined to individuals of the defective and degenerate class; and by a species of vicious circle the observation of such cases in inebriate reformatories and homes is now taken as a basis of argument, and has been accepted as giving an *a posteriori* proof of the original assumption that an inherent morbid tendency is the essential cause of alcoholic excess.

What makes this point of practical importance is that it goes to the root of the whole principle of State control of the inebriate. If inebriety is merely a manifestation of mental defect, then the inebriate is a proper subject for detention in an institution for the feeble-minded; the casual predominance of a single symptom—and that is all that inebriety means in such cases—can hardly necessitate treatment in a special reformatory, more particularly having regard to the small prospect of real gain, whether to the individual or to the community. On the other hand, a specially organised system of institutional care may reasonably be advocated for cases of environmental alcoholism. Such cases are certainly curable in the early stages of the alcoholic habit; they require special and individual treatment, and the expense of such treatment is justified by the restoration to society of useful citizens. Up to the present the legislation for inebriates has almost entirely failed, so far at least as its compulsory provisions are concerned, to reach this class of environmental alcoholics, and to this fact is largely due the public scepticism with regard to the utility of restraint as a curative measure. How limited the operation of the Act of 1898 has been in this respect is strikingly evident from the figures given in Dr. BRANTHWAITE'S report, from which it appears that during the 14 years the Act has been in force the total number of persons committed to reformatories has amounted to no more than 4280; and of this number only 756 were males, though alcoholism, and more particularly industrial alcoholism, is notoriously far more prevalent amongst men. The analysis of the different offences committed by these criminal inebriates is equally instructive from this point of view. To quote one illuminating example, we find that homicidal crime, the form of delinquency most characteristically related to alcoholism, was the ground of committal under the Act in exactly six instances in 14 years.

The conclusion to which the foregoing considerations must lead us is fairly obvious. The time has come for modifying very largely the direction and methods of the State control of the inebriate. The scope of legislation to that end should no longer be restricted to the congenital defective in whom inebriety is but one of many symptoms of debility and for whom there now exist other and more suitable methods of control; it should be directed to reach the chronic alcoholic whose organic disorders are the consequence of his intoxication and not the primary cause of his habit. These are the inebriates who are capable of reform, and they are also the inebriates whose intemperance represents the greatest positive and negative danger to society. But if legislation is to reach this class there must be some readjustment of our ideas on this question, and it will be necessary for those who are responsible for framing and administering the law with regard to inebriates to take a wider view of the problem, and not to answer all criticisms with such phrases as the "specific drink crave" and the "inborn tendency to inebriety."

Infantilism and Arrested Development.

IN all ages philosophers have tried to satisfy man's curiosity about himself by providing answers to his queries, Whence came I? Whither do I go? Lately man has begun to ask further questions, and the medical profession has been getting ready to answer him. He wants to know, amongst other things, why and how he grows from infancy to man's estate, a problem which clearly belongs to the domains of science rather than to those of philosophy or of religion. As yet science can answer but few of the conundrums which the phenomena of growth and development, witnessed throughout the animal kingdom, provide for solution. But certain rays of light have penetrated lately the darkness of our ignorance upon these matters, and a survey of what has been disclosed thereby is exceedingly valuable at this stage of progress. In his Hunterian lectures[1] on Infantilism Mr. HASTINGS GILFORD draws attention very appropriately—for we know that JOHN HUNTER was deeply interested in gigantism and similar anomalies—to certain pathological aspects of growth and development in the human race. The study of these is most important for the right understanding of the normal processes. There are two main avenues of scientific advance which have provided ways of access to these recondite mysteries. One is that which has been opened up by the study of eugenics, and especially by the labours of Professor KARL PEARSON and his school. The other is that provided by researches into the functions of the ductless glands, and into hormones, internal secretions, and similar bodies. The result of these investigations, and of the interest now taken in problems of growth, is that Mr. GILFORD has been able to propound a somewhat elaborate classification of infantilism, and to indicate the leading features which distinguish the different classes and subclasses from one another. It is quite probable that a good deal of this classification may have to be reconsidered, perhaps even abandoned, in a few years' time; but for the present it is a distinct step in advance simply to possess a tentative system by which the study of infantilism and allied disorders can be furthered, and by which different workers can correlate their observations made under varying conditions.

Mr. GILFORD begins with a very clear and necessary definition of infantilism and of the difference between it and dwarfism. The latter word implies merely conspicuous delay or arrest of growth, the former a similar imperfection of development. One, as he justly remarks, is purely quantitative; the other, qualitative. General infantilism usually, but not necessarily, connotes dwarfism also, and many dwarfs are infantile in some respects. But the conditions are distinct, and need not be coexistent. The complete classification of infantilism now put forward begins by separating off *evolutionary* or *phylogenetic* infantilism, which is that of immature or degenerate races. *Developmental* infantilism is the other main genus, and can be divided into the infantilism of *cells*, of *organs*, and of the *individual* as a whole. It is the latter which possesses the greatest interest, and requires further subdivision. Mr. GILFORD begins his classification of individual infantilism by explaining the difference between a fluctuation and a mutation. The former is a lesser degree of variation from the normal than the latter, which corresponds rather to what breeders know as a "sport," and which has been made familiar to us all by recent work in biology and heredity. The difference is quantitative rather than qualitative; and since there is no hard-and-fast distinction, it is evident that borderline cases must exist. Classification is further complicated by Mr. GILFORD'S unproved assumption that a fluctuation is a variation which can be attributed to definite causes, whereas a mutation cannot be explained except by the catchword of heredity. It is doubtless true that most cases of *symptomatic* infantilism—that is, infantilism which can be ascribed in part at least to causes other than heredity—are of lesser degree than those of *essential* or *idiopathic* infantilism, which is independent, so far as we know, of environment. To that extent the identification of symptomatic with mild, and of idiopathic with severe infantilism may be useful; but it does not afford a sound basis for a scientific classification, and appears to be dangerous in consequence. Symptomatic general infantilism may be *toxic*, *correlative*, or *deprivational*. Such poisons as those of syphilis, tuberculosis, malaria, and as yeast, opium, tobacco, lead, and mercury are cited as competent to produce the first of these varieties. Correlative infantilism may be due to disorder of some endocrine organ, as, for instance, cretinism following atrophy of the thyroid gland; or may be correlated with achondroplasia, muscular dystrophy, amentia, or similar defects in a manner which defies closer analysis. Deprivational infantilism is not definitely admitted to exist; indeed, Mr. GILFORD inclines to believe that infantilism cannot be produced by deficiency of food in quantity or quality.

---

[1] THE LANCET, Feb. 28th, 1914, p. 587; and March 7th, p. 664.

Essential infantilism occurs in two separate varieties—ateleiosis and progeria. The former is infantilism pure and simple; the latter is infantilism with superadded premature senile decay. These two extraordinary conditions have attracted much attention in the past few years, and their leading features have been described by several authors. Of ateleiosis, indeed, subspecies are recognised, according to the age at which the symptoms begin and to the sexual or non-sexual character of the infantilism. The consideration of this type of arrested development, which Mr. GILFORD regards as a throw back to some ancestral form, leads him to some interesting speculations concerning the descent of man and his evolution from non-human progenitors. It leads him also to a survey of ateleiotic cases, from which it can easily be seen that in many of them there is ground for suspecting endocrine deficiencies of various kinds. More than that, he frankly admits that in some cases it is difficult to make out whether ateleiosis or some endocrine defect—e.g., cretinism—is responsible for the infantilism. This surely demonstrates that there is no valid distinction between symptomatic and essential infantilism, and that the objection on logical grounds to a hard-and-fast distinction between them is borne out in practice. Nevertheless, ateleiosis is a useful label for a group of cases sufficiently alike to be provisionally classified together. The characteristics by which they can be identified are set forth by Mr. GILFORD with much clearness; and, indeed, he handles the whole subject of infantilism with a grasp and intimacy which will, we are certain, be of great value to his readers. His contributions to the study of infantilism had already clearly marked him out as a high authority on the subject, and that position he has now consolidated in these valuable Hunterian lectures.

Annotations.

"Ne quid nimis."

AMBULANCE SERVICE FOR THE METROPOLIS.

THE General Purposes Committee presented to the London County Council on March 10th further details of the proposed ambulance scheme for the metropolis, which has been in preparation since the Council decided that it could not accept the assistance of the Metropolitan Asylums Board.[1] The committee stated that the scheme now put forward could only be a tentative one, providing a service which in the future might be augmented or varied as experience might direct. The committee reaffirmed the opinion to which it has lately come, that existing appliances could only be used as supplemental to a service to be established by the Council, which must meet by itself the primary needs of the public. The committee gave some interesting figures supplied by the Commissioner of Police, showing the number of accidents and cases of illness in the streets during each of the 24 hours in the months of September, October, and November, 1913. It appeared that the greater number of accidents occurred during the luncheon hours and during the period from 5 to 7 P.M. The total number of cases in the three months were: Accidents, 4434 cases of illness, 1309. Without taking into account cases conveyed by the police to local doctors, of which no statistics were available, or accidents in factories and workshops, estimated by the Home Office at from 8000 to 10,000 per annum, the number of cases of accident and illness was estimated at 20,700 a year. The committee therefore proposed to provide for an estimated number of 27,700 cases, but as the dangers from street traffic were exceptionally great in London it was likely that this limit would be greatly exceeded. The scheme outlined by the committee provided for control by the fire brigade department, subject to the advice of the medical officer of health on medical questions. Six stations would be provided, three north and three south of the Thames—viz., at Fulham; Devonshire-mews, Harley street; Shoreditch; Southwark; Lee, S.E., and Brixton-hill, Lambeth. Each station would have one ambulance, except Shoreditch, which would have two. Temporary iron buildings would be provided so that removal would be easy if experience showed that better sites were possible. From these stations the committee believed that all parts of the county could be served. The ambulances would be petrol driven, as electrically propelled ones would not be suitable where the neighbourhood was hilly or long distances had to be covered. After exhaustive consideration of various types of stretcher appliances the committee decided in favour of the collapsible dhooly as used in Glasgow, with the addition of an attachment, only used in Glasgow at the Royal Infirmary, to keep the canvas rigid. Each ambulance would be equipped also with a plain board stretcher for use in cases such as fractured pelvis, where a collapsible stretcher might cause harm. In the ambulance itself a spring mattress covered with air beds would be provided. For the purpose of calling the ambulance the committee considered the existing telephone facilities would be sufficient, and it was hoped that residents whose premises were connected with the telephone system would place their telephones at the service of a constable in uniform, the houses of such residents being indicated, perhaps, by the attachment of a small notification plate. The committee asked for authority to proceed with a scheme on the lines indicated above, and received it after considerable debate.

---

THE RELATION OF SPEECH TO INTONATION AND RHYTHM.

THE question has frequently been discussed whether intonation is an integral or an independent element in articulate speech. The matter is only part of a wider subject—viz., the nature of the relations between articulate speech and the appreciation of tone and rhythm, as well as the expression of tone in singing speech. Cases have been recorded where patients suffering from motor aphasia have been able under the influence of musical stimuli to articulate words in song that otherwise they could not articulate at all. It is generally recognised, in fact, that normal individuals can often remember the words of a song only by singing the air. Sir William Gowers has somewhere said that the words of a song do not constitute articulate speech in the ordinary sense; they are merged in the melody and appear as its completion. There is an intimate association between articulate speech and musical tones. In one of his charming neurological lectures the late Professor Brissaud remarked that "le langage quel qu'il soit, n'est donc pas seulement parlé, il est chanté. Une phrase articulée a toujours sa melodie characteristique suivant qu'elle exprime la surprise, la colère, la joie, l'indignation, le doute, &c." He held that intonation is an earlier acquisition than articulation in the function of speech, and therefore that an intonation aphasia is not likely to be met with. This evolution theory finds apparent support in the facts that some idiots who cannot articulate can compose melodies, and that infants can reproduce melodies while they cannot form words. The late Professor Ballet thought that the expression of emotion, the elaboration of tone, and the articulation of words were three stages in one and the same process. There is no doubt that disturbances in the function of intonation, impairment of the appreciation of rhythm, and, generally, amusia, are closely associated with aphasia, and can be best understood by reference to the methods of investigation of that complex symptom. Nevertheless, the simplicity of the evolution theory constitutes perhaps its sole claim to consideration, and as yet no satisfactory hypothesis has been advanced to explain the facts which clinical observation discovers. There appears to be both a motor and a sensory defect of intonation, as well as a motor and a sensory arrhythmia. Isolated impairment of intonation, of appreciation of tone, or of rhythm may certainly occur, but whether these have independent localisations is a matter difficult of decision. In the *Neurologisches Centralblatt* for March 1st Dr. K. Agadschanianz, of St. Petersburg, has discussed the whole subject in a lucid fashion, and has described two cases at some length. In one of these a patient of 62 had a slight stroke producing hemiparesis of the left side. He had formerly been a good violin player. On examination he was found to have vocal and instrumental motor amusia, sensory and motor defect in the matter of rhythm, and incomplete word deafness and melody deafness. The second case was that of a doctor of medicine, aged 50, who had been a fine piano player. After a stroke involving the right side, probably of syphilitic origin, the paralysis cleared up entirely, but when he was examined subsequently the following condition was found. There was no instrumental amusia, but he could no longer sing, although he could speak. He understood spoken words imperfectly, but much better than familiar melodies played in his presence. Similarly he repeated spoken words much better than melodies played over for him; there was gross defect in the appreciation and reproduction of rhythm. Cases of this description do not support the evolution theory which makes articulate speech a more recent acquisition than emotional speech. It is probable that the two are anatomically independent, as they are psychologically. There is, further, some evidence to associate these faculties of rhythm and tone appreciation and expression with a localisation in the temporal lobes, a large cortical area the functions of only a small portion of which have been satisfactorily elucidated.

THE TREATMENT OF STERTOR.

A RECENT correspondence in the *Times* upon the subject of the "pains of death" brought to light a good deal of evidence in favour of a view which most practitioners of medicine early become impressed with—namely, that the apparent respiratory distress, which in a proportion of cases precedes death, is not in itself at all a painful experience to the patient. This view is one which anxious relatives often find it hard to credit, in face of the obvious dyspnœa exhibited by the sick person; they scarcely dare to believe an opinion to that effect expressed by the medical attendant, consolatory though it would be. The most nerve-racking form of this phenomenon is the noisy stertor familiarly known as the "death-rattle," though in fact it often does not denote speedy dissolution, nor, indeed, necessarily a fatal result at all. There is nothing in this form of respiratory difficulty which especially characterises the ebbing of life. Exactly similar noises are heard in the breathing of apoplexy and of cerebral tumour, in cases of drowning and of recovery from anæsthesia, and in several other conditions; and the exciting cause is usually the same —that is, a partial obstruction of the airway by loss of tone in the tongue and soft palate, with accumulation of mucus or other fluids. For pointing out the essential similarity of all these conditions the public and the medical profession are indebted to Sir Henry Morris, who has increased the obligation by emphasising the teaching of the late Dr. R. L. Bowles on the correct treatment of this form of stertor. It is a curious thing that Dr. Bowles's advice to place patients thus affected on their side, instead of allowing them to remain supine, and if necessary to hold forward the jaw, is so frequently neglected by medical men and nurses in the case of the dying; for it is universally taught as correct treatment during recovery from anæsthesia and in apoplexy. In the case of the stertor of those *in extremis*, this treatment is of service only in that it relieves the nervous strain upon the watchers in the sick room, already severe enough when a beloved relative or friend is crossing the bar. Even so, it is so simple and efficacious that it deserves to be more widely known and practised. There is, moreover, the further point that it may actually save life, though such cases must be rare, apart from those other conditions, such as apoplexy, in which its value is admitted by the medical profession. In this latter state, it is relevant to observe, the importance of Bowles' postural treatment is officially taught to every member of an ambulance first-aid course; so that there should be a considerable number of the general public to whom it is perfectly familiar.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

We are asked to state that hospitals in the County of London, or within nine miles of Charing Cross, desiring to participate in the grants made by this Fund for the year 1914, must make application before March 31st to the honorary secretaries, 7, Walbrook, E.C. Applications will also be considered from convalescent homes which are situated within the above boundaries, or which, being situated outside, take a large proportion of patients from London. Applications will also be considered from sanatoriums for consumption which take patients from London, or which are prepared to place beds at the disposal of the Fund for the use of patients from London hospitals.

THE NERVOUS COMPLICATIONS OF VARICELLA.

Varicella is usually regarded as a trivial disease, but occasionally it is accompanied by as grave complications as may occur in the other exanthemata. In the *British Journal of Children's Disease* for January Dr. Reginald Miller and Dr. James A. Davidson have contributed an important paper on the nervous complications, which are so rare that they are not mentioned in the majority of descriptions. They consider that there is good evidence that focal lesions of the central nervous system (encephalomyelitis) may occur. They report the following case of encephalitis. A boy, aged 2½ years, had a mild attack of varicella, in which the temperature did not exceed 100° F. On the fifth day he was found to be unable to stand or to talk distinctly, and there was some tremor of the limbs, head, and tongue. The tremor of the tongue passed off quickly, but four days later tremor was marked in the limbs. It was a slow rhythmic movement which prevented him from standing without support. The movements of the limbs were slow and stiff. The child was irritable and emotional. The reflexes were normal. The tremor in a few days gradually diminished until it was noticeable only during excitement and at the end of the month had practically disappeared. The child completely recovered but was thought to be more excitable than previously. Dr. Miller and Dr. Davidson considered that the symptoms were due to a destructive lesion of the cerebello-rubro-spinal system. A similar case has been reported by Caccia. A boy aged 3 years developed tremor on the fifth day of varicella. Its onset was preceded by two days' vomiting. He was unable to stand erect and speech was slow. Ankle clonus, increase of knee-jerk, and extensor plantar response were present on the right side. The cerebro-spinal fluid was sterile but contained 0·3 per cent. of albumin. After four weeks all the symptoms had disappeared. Caccia attributed them to encephalitis of the left cerebral hemisphere. Marfan has reported a case of varicella complicated by encephalitis affecting the oculo-motor nuclei, and Sir William Osler one complicated by hemiplegia. Poliomyelitis and peripheral neuritis have been recorded as complications, but the evidence is not altogether satisfactory. The occasional association of varicella with herpes zoster has been described by several writers. Other nervous complications recorded are convulsions, intracranial complications of otitis media, optic neuritis, hæmorrhagic pachymeningitis, and neuromyositis. Chorea has been noted to develop at the end of an attack of varicella, and tuberculous meningitis has been recorded as a sequel.

THE INTERNATIONAL CONGRESS FOR NEUROLOGY, MENTAL DISEASES, AND PSYCHOLOGY.

Our Bern correspondent writes that this congress will be held in Bern from Sept. 7th to 12th. The invitations for the congress are just being issued. The committee of organisation is presided over by Professor Du Bois, of Bern. Dr. Schnyder, Monbijoust. 31, Bern, is secretary, and will receive all applications of intending members. The fee is 25 francs and will include the official report. Facilities for railway travelling will be offered and arrangements made for trips in the most beautiful parts of Switzerland. Twenty-nine countries have declared their adhesion to the congress and have appointed delegates. The list of distinguished neurologists and psychologists who will open the debates is already complete and includes the following names: Professors Alzheimer, Ramon y Cajal, Sherrington, Pierre Marie, Donaldson, Edinger, Ehrlich, Mingazzini, von Stauffenberg, Biedl, Dejerine, and Oppenheim in the Neurological Section; Professors Gaupp, Gilbert Ballet, Strausky, Tamburini, Bechterew, Lépine, Isserlin, Redlich, Abderhalden, and Binswanger in the Psychiatric Section; and Professors Mott, Ladame, Ziehen, Morton Prince, Sante de Sanctis, and Imey in the Psychological Section. As 53 of these and their colleagues will speak on 11 neurological, 8 psychiatric, and 7 psychological subjects, only a limited number of special papers can be read, and these must be announced to the secretary by July 1st. The Swiss National Exhibition, which takes place this summer in Bern, affords an extra attraction. The President of the Swiss Republic is honorary President of the Congress.

HERPES SUPRALARYNGEUS.

Under this appellation Dr. Vittorio Grazzi, professor of laryngology in the University of Pisa, draws attention in a recent number of *Il Policlinico*[1] to an unusual form of herpes localised in the glosso-epiglottic folds, the free edge of the epiglottis, and the upper parts of the larynx. He quotes Morell Mackenzie and StClair Thomson as having on very rare occasions observed herpes in the upper parts of the larynx, and he has himself only seen four cases, three of which had not previously been diagnosed. Usually there are manifestations of herpes in other parts of the body, but the condition may be limited to the laryngoscopic region, while the fauces may not even be congested. The course of the disease is five or six days, and a prominent symptom is the severe burning pain, which is increased by deglutition, coughing, and speaking, so much so that one of the patients in order to satisfy his urgent craving for water was obliged to take up a position with head hanging over the edge of the bed and suck up the liquid through a straw. The diagnosis of this extremely rare condition is easy if there are other herpetic manifestations on the body, but in their absence the superficial character of the abrasions, their somewhat grouped arrangement, and absence of submucous infiltration, should be taken into account. The treatment adopted by Professor Grazzi was entirely symptomatic, and consisted in the direct application of ethereal solution of iodoform and alkaline inhalations with cocaine and menthol.

CASES OF SUPPOSED SYPHILIS HAVING PYREXIA AS THE ONLY CLINICAL SYMPTOM.

WRITING to the *Wiener Klinische Wochenschrift* Dr. Kraus makes the announcement that from observation of the inmates of a sanatorium for tuberculous patients he has come to the conclusion that there exist cases of a peculiar type which are commonly regarded as tuberculous, but are in reality syphilitic. The patients show intermittent pyrexia resembling that of pulmonary tuberculosis, with an occasional day or two of complete apyrexia The pulmonary symptoms found on examination of the chest are insignificant and do not correspond in their intensity to the severity of the pyrexia. There are generally loss of flesh or even emaciation, a slight hacking cough, and "hectic fever" lasting for months without being influenced at all by antipyretics; there are no direct symptoms of syphilis, but the Wassermann reaction is positive and antisyphilitic treatment causes a sharp rise of temperature, followed by a rapid and definite return of normal temperature. The patients generally have not had any marked symptoms of syphilis, and they may even be unaware that they have been infected. Dr. Kraus states that he discovered the first case by accident, but when searching later on amongst the cases he found three more within one year in the limited number of private patients admitted to his sanatorium. He says that he is not prepared to explain the pathology of this type of syphilitic manifestations, but wishes to draw the attention of the profession to a condition which appears to him to be by no means rare.

"THE FAMILY ENCYCLOPÆDIA OF MEDICINE."

AT a meeting held on Wednesday, March 11th, of members of the medical profession whose names have been associated with the recently published "Family Encyclopædia of Medicine" the following statement was, we are informed, unanimously agreed to:—

"As prominence has been given to our names in the advertisements of a book entitled 'The Family Encyclopædia of Medicine,' we desire to state—

1. That we are in no sense responsible for the plan or the scope of the book in question, or for the manner in which it has been introduced to the public.

2. That our sole connexion with it consists in our having obliged a fellow medical man by agreeing to correct, at his request made to us individually and privately, certain articles which he had in preparation for a book on domestic medicine.

3. We never gave authority for the use which has been made of our names.

We may add that we have received assurances from the editor and publishers of the book in question that our names will be removed from such future numbers as are not already in print.

It is needless to add that in no case was there any pecuniary consideration."

We understand that the legal position is still under consideration.

IT may seem rather premature to mention now the election for the Council of the Royal College of Surgeons of England which will not be held for three months, but the matter has been brought to public attention in more than one way. Mr. C. A. Ballance, Sir Henry Morris, and Mr. Richardson Cross are the three retiring members of the Council, and the latter two are, we understand, not presenting themselves for re-election. Another member of the Council, Mr. Jonathan Hutchinson, is retiring out of his due turn owing to pressure of hospital work. Already several candidates have announced their intention of standing, and these include Mr. W. G. Spencer, Mr. W. McAdam Eccles, Mr. William Thorburn, Mr. Stanley Boyd, and Mr. H. S. Pendlebury.

THE complimentary dinner to Surgeon-General Gorgas, which will be held on Monday, March 23rd, at the Savoy Hotel, London, W.C., will afford a great opportunity for the medical profession of this country to manifest their admiration for the scientific and administrative work which has made the opening of the Panama Canal possible. Sir Thomas Barlow will preside, and will be supported by Lord Bryce, Mr. Lewis Harcourt, and a highly representative body of medical men. Applications for tickets, price 25s. (with cheques), should be made to Mr. J. Y. W. MacAlister, at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W.

THE Fothergillian gold medal of the Medical Society of London for 1914 has been awarded to Dr. J. George Adami, F.R.S., professor of pathology in the McGill University, Montreal, for his work on Pathology and its Application to Practical Medicine and Surgery. It is hoped that Professor Adami will be present to receive the medal on the occasion of the conversazione on Monday, May 18th.

THE next meeting of the Medico-Legal Society will be held at 11, Chandos-street, Cavendish-square, W., on Tuesday, March 17th, at 8.30 P.M., when a paper entitled, "Must a Prison Governor keep Prisoners, not merely Safe, but Safe and Sound?" will be read by Mr. Roland Burrows.

AT the next meeting of the Section on Obstetrics and Gynæcology of the Royal Society of Medicine on April 2nd, at 8 P.M., Dr. Amand Routh will open a discussion on the Need for Research in Ante-Natal Pathology.

THE King and Queen will open the new premises of the National Institute for the Blind in Great Portland-street, London, on Thursday next, March 19th.

THE death is announced, at the age of 81, of Sir Francis Xavier Frederick MacCabe, F.R.C.P.I., for some years medical commissioner on the Local Government Board for Ireland.

ANNUAL REPORT FOR 1912 OF THE CHIEF MEDICAL OFFICER OF THE BOARD OF EDUCATION.

(Concluded from p. 702.)

Heart Disease and Rheumatism.

THE fifth section of Sir George Newman's report deals with heart disease and rheumatism, and brings out the fact that not enough is done to treat these conditions by school authorities. A very important table resumes the experience of the incidence of heart disease among 136,074 boys and 130,419 girls from 44 school areas, 13 being counties and 31 urban areas.

Organic and functional diseases of the heart are differentiated, and there are found to be 1111 cases of organic defect among boys and 1420 among girls, the percentages being 0·82 and 1·09 respectively, giving a mean percentage for boys and girls of 0·95. The highest total percentage recorded is 3·7 in Radnorshire (the total cases, however, are only 687), but percentages of 2·0 or over are recorded in Bradford, Heywood, Mossley, Rochdale, and Staffordshire. The lowest percentage recorded was 0·1 in Lincoln (total cases only 841), but Nottingham records 0·2 per cent., Plymouth 0·3 per cent., and Cheshire 0·2 per cent. Analyses of cases of organic defect show that in most areas mitral incompetence is most frequently recorded, but in Cambridge and Salford mitral stenosis was most frequent. A fact of very great importance is that only in 10 per cent. of children with defective hearts was any indication of imperfect health given. The indications (as given by Dr. Lila S. G. [illegible] were: f [illegible] 6; œde [illegible] 1; rheumatism, 1; growing pains, 1; and enlarged tonsils, 7.

The difficulty of the differential diagnosis of heart disease is considered with special reference to the work of Dr. H. M. Brown, who investigated 238 heart cases in Surrey, and Dr. H. W. Sinclair, who comments on the problem of the incidence of the malady in Essex. The re-examination of doubtful cases with the aid of the polygraph is recommended by the last-named observer. The correct diagnosis of heart disease is important, not only from the school point of view, but because of the great influence the opinion of a medical inspector may have on the child's future career beyond the school gates. And Sir George Newman recommends that "due weight should be given to the views of Dr. James Mackenzie" as set forward in a paper in the *British Medical Journal* for Dec. 21st, 1912. Dr. Mackenzie emphasises the "youthful type of irregularity" as a condition through which everyone at some time or another probably passes, and that functional murmurs are in themselves quite consistent with perfect health. In fact, according to Dr. Mackenzie, "a murmur or an irregularity is only of significance when it is associated with some manifest impairment of the heart muscle."

The causal connexion between rheumatism and heart disease is well brought out in an investigation of 2575 children between 5 and 13 years of age in Middlesex by Dr. A Ball, assistant medical officer. 611 of these children had a history of growing pains; 51 others gave a definite history of rheumatism. The rheumatic manifestations included acute and chronic rheumatism, scarlatinal and diphtherial rheumatism, erythema nodosum and chorea. Among the 662 rheumatic children there were 42 cases of organic heart disease, but among the 1913 non-rheumatic children only 16 cases of organic heart disease (congenital disease excluded). The probable causes among the non-rheumatic children were measles, whooping-cough, scarlet fever, and follicular tonsillitis.

It is very important to recognise the insidious signs of rheumatism in a child, and attention is called to the view of Dr. F. J. Poynton and Dr. A. Paine that the "only evidence of rheumatism may sometimes be a mysterious and persistent fever." But it must be recognised that the normal temperature of healthy children is by no means settled. An investigation by Dr. Alice W. Maclean in Staffordshire suggests that 99° F. is the true mean temperature of the ordinary school child, and that the range is from 97·2° to 100·6°.

Perhaps the most important aspect of the consideration of rheumatism and heart disease from the school medical service point of view is that of prevention; and in the prevention of rheumatism we are forced to rely largely on the education primarily of teachers and secondarily of parents in an understanding of the significance of growing pains, tonsillitis, chorea, and the vague rheumatic manifestations generally. Teachers are put first because it is comparatively easy to arrange for the consideration of rheumatism and heart disease in courses of hygiene for teachers, but the education of the parents must also be undertaken. This can be done by verbal advice at the time of medical inspection (if too many children are not crowded into one session and if parents attend), by distribution of printed matter, and by home visits by the school nurse or local health visitor. But as far as the distribution of printed matter is concerned this is only likely to be of secondary importance, for the reason that most parents will not trouble to read and understand printed medical instructions. Every medical man is familiar with the fact that very many people will not take pains to comprehend such matters as sick club certificates, vaccination papers, and school medical officers' "cards of advice." Although technically able to read, a large section of the population are not able to understand, and the little effort of mental concentration required to read an unfamiliar document is not put forth. This necessitates an educational campaign of oral teaching of parents, and the place where this can be most effectively done is at a school clinic, where the doctor, with the example of the parents' own child before him, will, at any rate, be sure of interest and of an effort at attention. The school teacher can also do a great deal with the parent, and the importance of dry boots and clothes can be usefully impressed in an object-lesson by having a supply of felt slippers and stoves or fires at which clothing can be dried.

How far children with heart disease should be excluded from the ordinary routine of work, exercises or play is a question that must be decided by reference to the commonsense of school life. Thus, as most children with heart disease will have to earn their own living, it is harmful and not helpful to wrap them round with the cotton-wool of invalidism. Strain should be avoided; swimming is usually contra-indicated, for example, and rough play and running up and down stairs carefully supervised, but ordinary Swedish exercises, with certain exceptions involving violent body movements, are good The teacher must, however, always be on the watch for signs of breathlessness and fatigue. Nothing is said in Sir George Newman's report of an observation that has sometimes been made—namely, that certain children with heart disease are abnormally rough and violent in their play. These cases will prove an extra strain on the teacher. It is also worth noting that one of the manifestations of heart trouble may be bad temper and irritability. As regards treatment, the opinion is expressed that not enough is done by local education authorities, and heart cases almost certainly require more medical supervision than is supplied by the usual re-examination of defective children. An observation clinic is what suggests itself. The report, however, suggests that a residential school of recovery is the best means available for the treatment of heart disease, and hopes that this will have its place in any scheme which is formulated.

School Meals and Nutrition.

The provision of meals for school children is now undertaken on such a large scale that we are justified in forming fairly definite conclusions as to the necessity, value, and limitations of this procedure. We must recognise that while food is the prime requisite for growth and the chief factor in nutrition, stimulation is also required and is chiefly represented by physical exercise and physical training. The beneficial results of open-air schools, for instance, must be ascribed not only to the open-air *régime* and the good food but also to the exercise which is the usual accompaniment of the open-air school routine.

Food and exercise must then be considered, by the school medical officer, together. With regard to the provision of meals the "Board are strongly of opinion that, where the work is regarded merely in the nature of temporary relief to be administered as cheaply as possible only in cases of extreme poverty, the benefits derived are bound to be insignificant and transitory." The report takes a strong line on this subject and definitely lays down that a feeding scheme should hold in view the permanent well-being of the child, and that the selection of children should depend not exclusively upon the poverty of the parents but upon the malnutrition of the child, this malnutrition being as definite a physical defect as any other which comes within the purview of school hygiene.

Before it is possible for the school medical officer to deal with school meals as one of the agencies under his control for treatment of malnutrition, the following conditions, laid down in Sir George Newman's report, must be complied with. The school medical officer must (1) have the right to nominate children for meals who are suffering from malnutrition due to "insufficiency or unsuitability of food"; (2) be consulted as to dietary provided; (3) have the right of inspecting meals at all stages of preparation and distribution; and (4) be consulted in all questions of doubt as to the necessity for retaining a child on the feeding list owing to its physical condition. That these conditions do not prevail in many places is unfortunately one of the commonplaces of school medical work. The Poor-law aspect of the matter, with a strong dash of the Poor-law spectre "deterence," is all too frequently allowed to dominate the educational aspect. We gather from this report that all over the country the organisation of meals is in an early and primitive condition, although the total of meals given and children fed is a figure of large dimensions. Thus in 1912–13 over 19 millions of meals were given in England and Wales, an increase of more than 2¾ millions over the previous year. The number of children fed was over 300,000, and as there are about 10 per cent. of the total 6,000,000 children in attendance at school, or 600,000 suffering from malnutrition, this figure shows that only half of those requiring food are, in fact, receiving it for longer or shorter periods. Each child fed received on the average something over 60 meals, and the period under consideration included the coal strike, which compelled a number of authorities who had not previously done so to enter upon feeding schemes.

How diverse is the practice of different authorities with regard to provision of meals is seen clearly by a glance at the statistical table which sets forth the total expenditure of those who availed themselves of their powers under the Education (Provision of Meals) Act, 1906. Firstly, the table shows that less than one-third of the 317 authorities availed themselves of their powers. Secondly, of those who did make use of their powers, Keighley, Kidderminster, Mossley, Heston and Isleworth, and Kent spent only £4, £5, £8, £8, and £9 respectively, while London, Bradford, Leeds, East Ham, the West Riding of Yorkshire, and Tottenham spent respectively £44,605, £4139, £3348, £1059, £1437, and £959. It is not possible to draw any very definite statistical conclusion from these tables. But when we add to the divergencies of method our knowledge of the lack of ordered medical supervision of the meals and of their inadequacy from the standpoint of nutrition we have to describe the administration of the Education (Provision of Meals) Act, 1906, as very seriously unsatisfactory and only redeemed from wholesale condemnation by the efforts of such authorities as Bradford, who do try to cope with the existing problem as it stands, and not on theoretical grounds. As to the kind of meal necessary there seems very little doubt. A good midday meal is best and should be physiologically calculated to make up the presumed deficiencies of the diet at other times. Experience in secondary schools confirms this, the London report on secondary school feeding being summed up in the words, "Improvement in physique has gone *pari passu* with the improvement of the midday meal."

Physical Training and Juvenile Employment.

Both with regard to physical training and the employment of children under and just over 14 years the sphere of medical inspection is an obviously enlarging one. Field games, swimming, and remedial exercises are matters especially belonging to the school medical officer's province. But the whole of physical training is or should be within the ambit of the organisation of the school medical service. The section dealing with physical training contains a useful and detailed description of exercises and apparatus (with diagrams), and should help on the movement towards greater efficiency in this branch of teaching.

The section dealing with juvenile employment brings out very clearly indeed the evils of this practice. There are no less than 211,000 children under 14 years who at any one time during the year have obtained total exemption from school attendance, and there are 35,000 "half-timers." Apart from this, however, a very large number of children do some kind of work out of school hours and suffer correspondingly with the nature of that employment and the severity of the labour involved. The effects are so grave that the Board of Education suggest that all employed children should be entered upon a special register and examined periodically by the school medical officer as "specials."

Conclusions.

This report is a great searchlight that flashes into the recesses of our social order, and by enabling us to see clearly and in detail what is wrong gives us the opportunity of doing what is necessary to put the wrong right The whole of the report consists of the two things—a display of existing wrong conditions and detailed proposals for the application of knowledge to put those conditions right. It may be, not improbably, that, in a future which has forgotten the party cries and surface turmoil of the present, the application of science to life, which is the great theme of Sir George Newman's report, may appear as one of the outstanding achievements of our generation.

IMPERIAL BUREAU OF ENTOMOLOGY.

THE Earl of Cromer, O.M., as chairman of the Entomological Research Committee, instituted some years ago,[1] has presented his second report to the Secretary of State for the Colonies (the Right Hon. L. Harcourt, M.P.), and has announced that in future a report will be made every year. The chief feature of the work in 1913 has been the actual establishment of the Imperial Bureau of Entomology. It has consequently been decided to discontinue the use of the title "Entomological Research Committee," as confusion seemed likely to arise from the existence of what were apparently two separate organisations in London working at the same subject. The Entomological Research Committee has, therefore, now become the managing committee of the Bureau, and Mr. Guy Marshall, who held the appointment of scientific secretary to the Entomological Research Committee, has been made director of the Bureau, the expenses of which are met by contributions from the Imperial Government, Canada, India, the Australian Commonwealth, the West African Colonies, Zanzibar, and the other Governments concerned. The whole organisation is singularly comprehensive, and is proving of great utility, not only to countries within the Empire, but also to those without. The "Review of Applied Entomology," issued by the Bureau every month, is making satisfactory progress, and the material available for publication is steadily increasing, more especially on the agricultural side.

The Distribution of the Stegomyia Mosquito.

The Bureau has made considerable progress towards obtaining a complete set of the various laws and regulations against injurious insects which have been promulgated in the British Dominions and colonies, and arrangements are now being made to collate and summarise them in a convenient form. The Bureau has also extended the sphere of its activities in another important direction. Major S. P. James, of the Indian Medical Service, was recently deputed by the Indian Government to visit South and Central America and report on the possibility of yellow fever being introduced into India by the increased traffic across the Pacific Ocean which will inevitably follow the opening of the Panama Canal.[2] It appeared from his report that there is little or no knowledge, not only of a sure method of diagnosing the disease, but also of the presence or absence—and of the distribution if present—in eastern lands of the mosquito which is known to convey the disease (stegomyia fasciata). It also appeared that there is a similar want of knowledge as to whether stegomyia scutellaris, another very widely distributed and abundant species of mosquito of the same genus, carries the disease or not, and as to many other matters of capital importance affecting the etiology and prevention of yellow fever. Should it be necessary, therefore, to deal with an outbreak of yellow fever in a new territory, it is evident that this want of knowledge would greatly hamper and delay efficient and enlightened administrative action. The coöperation of the Bureau was invited on behalf of India and the eastern colonies, and the Bureau has undertaken to collect information as to the distribution of the stegomyia mosquito in the countries which are likely to provide ports of call for vessels from infected districts.

---

[1] THE LANCET, Sept. 18th, 1909, p. 878; Dec. 7th, 1912, p. 1606.

[2] THE LANCET, Jan. 31st, 1914, p. 329.

As a preliminary measure the Bureau has asked to be furnished with all information available as to the distribution of mosquitoes generally, and of the genus stegomyia in particular, in the French, German, Japanese, American, and Dutch possessions in the Far East and the Pacific, and to be provided with collections of mosquitoes from these localities. The question of sending out an entomologist specially to collect information in those places from which none can now be obtained may be considered at a later date in the light of the knowledge thus gained. Dr. A. T. Stanton has kindly offered to supply the Bureau with collections and data from the Federated Malay States, and has written to various correspondents in the East asking them to do the same. He is shortly visiting Siam and Indo-China, and will utilise the opportunity to further the inquiry. Mr. J. C. Moulton, of the Sarawak Museum, has agreed to assist in Borneo, and Mr. P. D. Montague, of Cambridge, who has just started on a zoological expedition to New Caledonia, has consented to collect mosquitoes both there and in any parts visited *en route*. In Hong-Kong the medical authorities have already made a preliminary mosquito survey.

Glossina Morsitans.

The committee are also taking steps to render assistance in another important direction. Arrangements have been made with Mr. W. F. Fiske, one of the most capable entomologists lately in the service of the United States Bureau of Entomology, to carry out, under the direction of the Royal Society and at the expense of the Government of Nyassaland, a thorough investigation of the bionomics of the tsetse fly, glossina morsitans. In the first instance, however, he is investigating the allied species, glossina palpalis, in Uganda as a preliminary. The committee, with Mr. Andrew Carnegie's consent, are placing at his disposal one of the scholars who are being trained in American methods of entomology with the help of funds provided by Mr. Carnegie for the purpose. It is to be hoped that this will be the beginning of an organised campaign against the various species of tsetse fly throughout Africa, and the committee are now considering whether they cannot render further assistance by employing the two entomologists who are working under their direction in East and West Africa respectively entirely on investigations connected with tsetse flies. It is clear that the discovery of any effective method of dealing with these flies in Africa would have the most far-reaching effects on the prosperity and progress of that continent.

Other Investigations.

The report gives many further details of the work of the Bureau, and also points out that the question of the identification of parasitic hymenoptera is becoming a pressing one owing to their great importance in the control of injurious insects. Unfortunately, the number of reliable specialists working at these groups is extremely limited, and they already have more work than they can do. The committee therefore propose that one or more of the assistants working under the director of the Bureau should devote themselves to this group of insects. For the identification of the African tachinidæ (a very useful family of parasitic flies) the committee have been fortunate in securing the generous assistance of Dr. Villeneuve, of Rambouillet, who has kindly agreed to name all the material submitted to him.

The Secretary of State for the Colonies, in acknowledging the receipt of Lord Cromer's report, expresses high appreciation of the work of the committee and the rapidity with which it is expanding. He adds that he has readily given his approval to increases of staff recommended by the committee, a[illegible] the trustees of the B[illegible] accommodation for [illegible] personal assistants.

MEDICAL SOCIETY OF LONDON:

THE ANNIVERSARY DINNER.

THE 141st anniversary dinner of the Medical Society of London was held at the Whitehall Rooms, Hôtel Métropole, on March 4th. The chair was taken by Sir DAVID FERRIER, F.R.S., the President, who was supported by a large company of Fellows and guests. Among those present, in addition to the speakers mentioned below, were Mr. Martindale Ward, Master of the Society of Apothecaries; Surgeon-General Sloggett, Director-General of the Army Medical Service; Colonel Bruce Skinner, Commandant of the Royal Army Medical College; Sir Alfred Pearce Gould, Dean of the Faculty of Medicine in the University of London; Surgeon-General Arthur May, Medical Director-General of the Royal Navy; Sir Richard Douglas Powell; Professor Howard Marsh, Master of Downing; Sir T. Clifford Allbutt, Regius Professor of Physic in the University of Cambridge; Sir John Tweedy; Mr. D'Arcy Power; Dr. J. Mitchell Bruce; Sir R. Havelock Charles; Dr. Samuel West; Dr. F. W. Mott; Mr. C. A. Ballance; and Sir John Broadbent.

After the loyal toasts had been honoured, the PRESIDENT proposed the toast of "The Medical Society of London," which he coupled with the name of Mr. V. Warren Low, one of the trustees. He made allusion to several early patrons of the society—in particular Lettsom, a founder and generous benefactor, and the two Fothergills, John and Anthony. He voiced the regret of the Fellows that through the illness of Dr. F. M. Sandwith, the delivery of the Lettsomian Lectures for 1914 had been postponed until the summer, and announced that the Fothergill Medal had been awarded this year to Professor J. G. Adami, of Montreal, for his researches in pathology as applied to medicine and surgery. Originally, said the President, their membership was confined to 30 physicians, 30 surgeons, and 30 apothecaries; but now, in its 141st year, the society numbered nearly 700.

Mr WARREN LOW prefaced his reply by maintaining that the records of the society were themselves a better response to that toast than any speech could be. He believed that the Medical Society of London was especially valuable because it provided a common ground in homely surroundings upon which the physician, the surgeon, the general practitioner, and, he might add, the crank could meet and exchange views. He rather deprecated over-organisation and the set discussion wherein the opening speech was often followed by a number of admirable papers quite off the track.

Dr. F. DE HAVILLAND HALL, in submitting the toast of the kindred societies, paid compliments to the 13 presidents who were among them that evening. The friendly competition between their society and the Royal Society of Medicine had been productive of good to them all.

The response was entrusted to Sir Francis Champneys, President of the Royal Society of Medicine, and Earl Russell, President of the Medico-Legal Society.

Sir FRANCIS CHAMPNEYS said that the body which he represented had passed through the storms incidental to the settling down of the 23 amalgamated societies into one working organisation. It was now on the best of terms with the Medical Society of London, which in his matured opinion had done wisely in standing out, for unlike the various constituent societies it was complete in itself and by joining would have disappeared. It was the mother of all the medical societies, and to have swallowed it up would have been matricide and cannibalism.

Lord RUSSELL, in a humorous speech, mentioned the horrible specimens in bottles which were sometimes brought forward by medical members at meetings over which he presided, and the sensational discussions which occasionally embarrassed the mere legal members of the Medico-Legal Society. He concluded by emphasising the need which there was nowadays for the doctor and the lawyer (with whom he included the politician who made the laws) to understand each other better so that they might cooperate for the public good. As an example he quoted the legislative and administrative problems connected with uncertified and uncertifiable lunatics.

Mr. C. B. LOCKWOOD, in proposing the health of the guests, made brief kindly references to each of the visitors, and in particular spoke of the honour which American surgery had paid to British surgery by asking the President of the Royal College of Surgeons of England to help in the inauguration of the College of Surgeons of America.

Sir RICKMAN GODLEE, in response, said that this was the third time he had had to reply for the guests, and it was impossible for him to make three serious speeches upon the same subject before the same assembly, although the approved American method of after-dinner oratory, consisting of an immediate and abrupt plunge into anecdote, had its difficulties.

The Mayor of Marylebone, the Rev. J. A. BEAUMONT, who also replied, related how he himself had started as a medical student. He looked forward to a working partnership in the future between the priest and the medical man. The association between the two professions, now so much less close than in former days, still held out hope of future possibilities.

The health of the President was proposed in affectionate terms by Professor ARTHUR KEITH, F.R.S., President of the Royal Anthropological Institution. Sir David Ferrier and he were born within a mile of each other, he said, and their President used to be held up to him as a model of what a young man should be. Contrary to what some might have said, Professor Keith was sure that it was an advantage in London to have been born in the North. The toast was warmly received, and after Sir DAVID FERRIER had replied the proceedings closed with a hearty vote of thanks to Dr. R. A. Young and Mr. G. E. Gask, the honorary secretaries, and Mr. George Bethell, the registrar, for their successful efforts on behalf of the society.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the twentieth meeting of the Royal Commission on Venereal Diseases evidence was given by Mr. C. A. Ballance, chief surgeon of the Metropolitan Police and surgeon to St. Thomas's Hospital.

Mr. Ballance said that the amount of venereal disease among the police was very slight. Formerly police officers reporting themselves sick from venereal diseases were looked upon as defaulters, their pay was stopped usually for a week, and they were generally put on half pay afterwards. In May, 1911, the system was entirely changed, and it was decided that venereal disease should be treated like ordinary sickness. The result has been that most of those affected with venereal disease have reported themselves sick to the divisional surgeon and have not tried to keep it secret. As many cases as can be accommodated are sent to the military hospital, but if that hospital is unable to receive them they are sent to the nearest large general hospital. Mr. Ballance thought that the number of syphilitic patients had increased, but that this was due to the fact that the men appreciated the treatment at the military hospital; he did not think that there was any increase of prevalence of the disease amongst the force. The change of system had had the good effect of securing treatment at an early stage. Out of 83 constables reported as treated at the primary stage at the military hospital only 3 developed secondary symptoms. Out of 116 other consecutive cases only 8 had had clinical relapses. He considered that these figures were quite wonderful.

From his experience at St. Thomas's Hospital Mr. Ballance thought that in recent years there were fewer serious venereal cases than formerly; this he thought was due to the early treatment of the cases instead of their being neglected or untreated, as in the old days. He very much doubted whether the actual prevalence had diminished. Questioned as to the use of salvarsan, he said that in the cases in which he had used it he had never seen any danger arise from it, only good.

Evidence was also given by Mr. Richardson, who said that he was an M.D. of Cincinnati, in behalf of the National Association of Medical Herbalists of Great Britain.

At the twenty-first meeting evidence was given by Dr. Brian O'Brien, medical inspector of the Local Government Board for Ireland. Dr. O'Brien said that for the purposes of his evidence he had visited all the larger towns in Ireland and many of the smaller ones, as well as a certain number of rural districts, and that the impression made upon him was that there was a decline of venereal disease in the country districts and small towns. It was his opinion that venereal disease, syphilis especially, is almost non-existent in the rural portions of Ireland and uncommon in the smaller towns. There was special prevalence in Dublin, and among the causes contributing to this prevalence he mentioned poverty, bad housing, and the fact that Dublin is the refuge of people from the greater part of Ireland who are doing no good for themselves. There was also some prevalence of the disease in Belfast, but to a much less extent than in Dublin. The treatment of the diseases in Ireland at the present time was, he thought, very inadequate. His two main recommendations were that means should be provided for improved diagnosis and that institutional treatment should be subsidised. There would be advantage, he thought, in providing out-patient departments of general hospitals which would be open in the evening, and a considerable number of men might thus be attracted to be treated promptly and efficiently. He was, however, inclined to doubt whether a very large proportion of the women would present themselves for treatment. Dr. O'Brien was opposed to the notification of venereal disease; he did not think that the medical profession would be willing to notify, and if they did fewer people would go to them for treatment.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8484 births and 5497 deaths were registered during the week ended Saturday, March 7th. The annual rate of mortality in these towns, which had been 15·6, 15·0, and 15·1 per 1000 in the three preceding weeks, further rose to 15·8 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 16·7, against 16·5 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5·6 in Eastbourne, 8·1 in York, 8·2 in Hornsey, 9·0 in Cambridge, and 9·3 in Willesden, to 21·8 in Ipswich, 22·0 in Bury, 23·1 in Middlesbrough, 24·4 in Warrington, and 24·9 in Rochdale.

The 5497 deaths from all causes were 241 in excess of the number in the previous week, and included 425 which were referred to the principal epidemic diseases, against 397 and 413 in the two preceding weeks. Of these 425 deaths, 134 resulted from whooping-cough, 118 from measles, 60 from diphtheria, 59 from infantile diarrhœal diseases, 34 from scarlet fever, and 20 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week did not exceed 1·2 per 1000, and was equal to that recorded in the preceding week. The deaths attributed to whooping-cough, which had been 129, 110, and 115 in the three preceding weeks, further rose to 134 last week, and caused the highest annual death-rates of 1·4 per 1000 in Tottenham and in Smethwick, 1·5 in Edmonton, 1·6 in Leicester, 1·8 in Devonport, 2·2 in Rochdale, and 2·6 in Darlington. The deaths referred to measles, which had been 89, 115, and 101 in the three preceding weeks, rose to 118 last week; the highest death-rates from this disease were 1·4 in Ipswich, in Nottingham, in Warrington, and in Cardiff, 1·9 in West Ham and in Barnsley, 2·6 in Swansea, and 4·7 in Burnley. The fatal cases of diphtheria, which had been 64, 52, and 72 in the three preceding weeks, declined to 60 last week, of which 16 were registered in London and its suburban districts, and 3 each in Portsmouth, Plymouth, and Birmingham. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had risen from 66 to 83 in the four preceding weeks, fell to 59 last week, and included 23 in London, 5 in Stoke-on-Trent, and 5 in Sheffield. The deaths referred to scarlet fever, which had been 37, 33, and 34 in the three preceding weeks, were again 34 last week; 7 deaths occurred in London, and 3 each in Birmingham, Manchester, and Middlesbrough. The fatal cases of enteric fever, which had been 14, 17, and 8 in the three preceding weeks, rose to 20 last week, of which 4 were registered in London, 3 in Manchester, 2 in Stoke-on-Trent, and 2 in Bradford.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had declined from 3599 to 3392 in the five

preceding weeks, had further decreased to 3307 on Saturday last; 340 new cases were admitted during the week, against 428, 351, and 401 in the three preceding weeks. These hospitals also contained on Saturday last 1267 ca
f whooping cough, 99 of measles
1 of small-pox. The 1350 deaths
were 128 in excess of the number
and corresponded to an annual death-rate of 15·6 per 1000. The deaths referred to diseases of the respiratory system, which had declined from 425 to 243 in the five preceding weeks, rose to 260 last week, but were 193 below the number registered in the corresponding week of last year.

Of the 5497 deaths from all causes in the 97 towns, 183 were attributed to different forms of violence, and 402 were the subject of coroners' inquests. The causes of 37, or 0·7 per cent., of the total deaths were not certified either by a

Queen's Hospital, Bir
for the Blind, Edgbaston.—As the result of a compromise in a recent law suit in which a will was disputed it was decided to give £10,000 to a medical charity, the Jervis-street Hospital, Dublin, being the fortunate institution chosen.—Sir Frank Mappin has sent £1000 towards the Sheffield Radium Fund, which now amounts to over £4000.—Miss Burrell, of Botley, has given a donation of £1500 (additional to £5000 recently given) towards the reconstruction of the Hampshire County Hospital.

ROYAL EDINBURGH MEDICAL SOCIETY: ANNUAL DINNER.—This dinner was held in the society's hall under the chairmanship of Dr W. A. Alexander, the senior President. Mr Rutherford Morison, F.R.C.S., was the guest of the evening, and there was a large and representative company present. After the loyal and patriotic toasts had been honoured, the chairman proposed the health of Mr Rutherford Morison. In response Mr Morison gave some entertaining reminiscences of affairs in the Royal Infirmary during his early years in Edinburgh. He also gave some interesting impressions of Lister. If the vote of the students had been taken at that time as to who was the best surgeon in Edinburgh he was sure that Lister would have taken a back seat indeed. His colleagues had no hesitation in saying that they thought his theories, as they called them, all nonsense, and unworthy of consideration. Very few of the public knew anything about his work, and he was said to have had but few patients. A few at that early time saw that he had something to teach which could not be learnt elsewhere. He himself was a clerk to Lister for three months, and during that time the chief did not operate oftener than once a fortnight. His wards were full—40 to 50 beds—and they were filled with cases of accident, ulcer, tuberculosis, and the few cases which had been operated upon. He was very devoted to these tuberculosis cases, and would keep them in for months. Mr. Morison then reviewed some of the modern developments in surgical science.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of his late Majesty's Order in Council of August 11th, 1903, Surgeon Gerald Arthur Bradshaw has been allowed to withdraw from His Majesty's Naval Service with a gratuity.

The following appointments have been notified:—Deputy Surgeons-General: A. G. Wildey to the *Victory*, additional, for Haslar Hospital, and G. A. Dreaper to the *Vivid*, additional, for Plymouth Hospital. Fleet-Surgeons: W. Jackson to the *Venerable;* E. A. Penfold, P. H. Boyden, M. J. Smith, E. Arkwright, J. Shand (lent), and F. W. Parker (lent), all to the *President*, additional, for Senior Medical Officers' Course, at the Royal Naval Medical School, Greenwich; and E. H. Meaden to the *Impregnable*, temporary. Staff-Surgeon: H. W. B. Shewell to the *President*, additional, for Senior Medical Officers' Course at the Royal Naval Medical School, Greenwich. Surgeon I. S. Gabe to the *Devonshire.*

ARMY MEDICAL SERVICE.

Colonel William G. Macpherson, C.M.G., K.H.P., to be Deputy Director-General, and to be granted the temporary rank of Surgeon-General whilst so employed, vice Surgeon-General W. Babtie, V.C., C.M.G. (dated March 6th, 1914).

ROYAL ARMY MEDICAL CORPS.

Captain Francis M. M. Ommanney retires receiving a gratuity (dated March 11th, 1914).

Surgeon-General W. Babtie, V.C., C.B., C.M.G., has embarked for a tour of service in India.

Lieutenant-Colonel R. W. Wright has been selected for the higher rate of pay under Article 358 of the Royal Warrant of Pay and Promotion. Lieutenant-Colonel A. T. I. Lilly has been granted six months' general leave of absence in India. Lieutenant-Colonel C. W. H. Whitestone has arrived home for duty from India. Lieutenant-Colonel H. C. Thurston, C.M.G., has been transferred from medical charge of the Royal Military College at Sandhurst to the Aldershot Command. Lieutenant-Colonel B. J. Inniss has embarked for a tour of service in India. Lieutenant-Colonel T. B. Winter has been appointed to hold charge of the Military Hospital at Canterbury. Lieutenant-Colonel T. du B. Whaite has embarked for a tour of service with the Third (Lahore) Division of the Northern Army in India.

Major R. L. Popham has embarked for a tour of service in India. Major H. F. Shea has been selected for appointment as Specialist in Advanced Operative Surgery to the Third (Lahore) Division. Major J. S. Bostock has taken up duty at Aldershot. Major E. F. Q. L'Estrange has arrived home for duty from India. Major J. D. G. Macpherson has been appointed to the Northern Command. Major C. B. Martin has been appointed to hold medical charge of the Royal Military College at Sandhurst. Major F. S. Penny has arrived home from Hong-Kong for duty. Major F. E. Gunter has been appointed to the Southern Command. Major C. J. Holmes has been appointed to hold medical charge of the Depôt at Lancaster. Major R. McK. Skinner has embarked for a tour of service in India. Major A. D. Waring has been transferred from the Military Hospital at Hilsea to Gosport. Major J. H. Robinson has taken up duty at Peshawar. Major V. J. Crawford has arrived home for duty from the Military Hospital at Curepipe, Mauritius. Major B. F. Wingate has been appointed to the London District. Major E. E. Powell has been appointed to the Military Hospital at Ambala Cantonment. Major F. M. Mangin has been transferred to Poona Cantonment from the Military Hospital at Allahabad Cantonment. Major E. E. Parkes has embarked for a tour of service in India. Major N. H. Moss has been placed in charge of the Bacteriological Research Laboratory at headquarters, Fyzabad Cantonment. Major L. F. Smith has been transferred from the Military Hospital at Nowshera Cantonment to the Aden Brigade. Major S. A. Archer has arrived home for duty from India. Major M. MacG. Rattray has been transferred from the Military Hospital at Shorncliffe to Woolwich.

Captain T. C. C. Leslie has embarked for a tour of service in India. Captain T. W. Browne has been appointed to hold medical charge at Tipperary Military Barracks. Captain R. Storrs has been appointed to hold medical charge at Dorchester. Captain W. W. Browne has taken up duty at Ahmednagar Cantonment. Captain R. H. MacNichol has embarked for a tour of service at Malta. Captain J. J. O'Keefe has been appointed to the Military Hospital at Chatham. Captain R. Rutherford has arrived home from the Military Hospital at Singapore. Captain J. E. H. Gatt has been transferred from the Military Hospital at Cawnpore to Benares Cantonment. Captain A. H. Hayes has embarked for a tour of service in India. Captain G. W. G. Hughes has taken up duty at the Military Hospital, Plymouth. Captain T. S. Dudding has been appointed to the Bombay Brigade. Captain J. G. Carmichael has embarked for a tour of duty at Malta. Captain N. Low has joined the Colchester District. Captain M. Keane has embarked for a tour of service in India. Captain A. W. Byrne has been selected for appointment as Deputy Assistant Director of Medical Services (Sanitary Branch) to the Third Lahore Division. Captain E. D. Caddell has arrived home from Aden. Captain E. C. Stoney has been transferred from the Military Hospital at Shwebo to Bhamo. Captain P. C. Field has been transferred from the Military Hospital at Alexandria to Cairo. Captain A. N. R. McNeill has arrived home from Mauritius. Captain W. E. Marshall has been appointed to Cork District. Captain A. H. Douglass has embarked for a tour of duty in the Sierra Leone Protectorate. Captain W. H. O'Riordan has been transferred from the Military Hospital at Dehra Dun to Rawal Pindi Cantonment. Captain C. H. Denyer has been appointed for duty on board the transport from India s.s. *Plassy*.

Lieutenant E. C. Beddows has been transferred from Kildare and appointed to the Military Hospital at the Curragh Camp. The following Lieutenants have embarked for a tour of service in India: R. Davidson, R. K. Mallam, W. MacNaughtan, D. T. M. Large, M. Burnett, A. Hood, C. J. Blaikie, and J. R. M. Frobisher. Lieutenant R. C. Carlyle has been transferred from London to the Military Hospital at Caterham. Lieutenant G. F. Allison has been appointed to the Military Hospital at Strensall. Lieutenant W. L. Webster has embarked for Egypt. Lieutenant R. E. Porter has been transferred from Cork to Limerick. Lieutenant E. C. Lang has taken up duty at the Military Hospital, Curragh Camp. Lieutenant D. W. Bruce has been appointed to the Third (Lahore) Division of the Northern Army for a tour of duty. Lieutenant C. H. H. Harold has taken up duty at the Military Hospital, Ambala Cantonment, as Specialist in Dermatology and Venereal Diseases. Lieutenant E. G. S. Cane has been selected for appointment as Specialist in the Prevention of Disease in charge of the *Bacteriological Research Laboratory at Colaba, Bombay.*

INDIAN MEDICAL SERVICE.

Surgeon-General W. B. Bannerman, C.S.I., has rejoined at Madras.

Lieutenant-Colonel G. McI. Smith has been appointed Civil Surgeon at Ludhiana. Lieutenant-Colonel W. E. Jennings has been appointed Health Officer of the Port of Bombay. Lieutenant-Colonel B. J. Singh, Inspector-General of Civil Prisons, has been granted combined leave of absence for eight months. The services of Lieutenant-Colonel H. W. Pilgrim have been replaced at the disposal of the Commander-in-Chief in India. Lieutenant-Colonel A. W. Dawson has taken up duty at Roorkee.

The services of Major W. G. Richards have been placed temporarily at the disposal of the Government of Madras Presidency. Major J. W. Watson has taken up duty at Bhopal as Agency Surgeon. Major T. A. Granger has been selected for advancement to the rank of Lieutenant-Colonel. Major R. M. Carter has been selected by the Government of Bombay Presidency for employment in the Civil Medical Department. Major J. R. J. Tyrrell has been selected for appointment as Civil Surgeon to the Khyber District. The services of Major A. Gwyther have been placed temporarily at the disposal of the Director-General for special duty in connexion with an inquiry into leprosy. Major W. Glen Liston, C.I.E., has reverted to his substantive appointment as Director of the Bombay Bacteriological Laboratory. Major J. G. Swan has been selected for appointment as Civil Surgeon at Dalhousie.

Captain C. A. Gill on return to India has been appointed Chief Malaria Officer in the Punjab. The services of Captain E. B. Munro have been placed at the disposal of the Government of Bengal Presidency for employment in the Civil Medical Department. Captain L. Cook, officiating civil surgeon at Sambalpur, has been appointed to officiate as Civil Surgeon at Puri. Captain S. B. Mehta has arrived home on leave of absence from India. Captain C. H. Cross has been appointed Probationary Chemical Examiner to the Madras Government. Captain J. Smalley has been appointed Assistant to the Civil Surgeon at Poona, vice Captain A. F. Hamilton granted leave of absence. Captain F. O'D. Fawcett has taken over Medical Charge of the 1st Gurkha Rifles.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants to be Captains: Sarsfield J. A. H. Walshe (dated Feb. 15th, 1914), and Clarence E. Greeson (dated Feb. 18th, 1914).

Lieutenant John Fraser resigns his commission (dated March 7th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd East Anglian Field Ambulance, Royal Army Medical Corps: Lieutenant Alexander Graham to be Captain (dated Jan. 7th, 1914).

3rd Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant James Barkley to be Captain (dated Feb. 3rd, 1914).

THE NAVAL MEDICAL SUPPLEMENTAL (COMPASSIONATE) FUND.

It is announced that application will be made in the present session of Parliament for an Act to make better provision with respect to the Naval Medical Supplemental [illegible] *proposed to appoint trustees comprising representatives of* the Admiralty and the Naval Medical Society, to place the control of the Fund under the Royal Naval Medical Club and representatives of the Admiralty, [illegible] al Service [illegible] approved [illegible] widows and [illegible]. Such an [illegible] ts relating [illegible]

THE HEALTH OF THE GERMAN NAVY, 1910-11.

[illegible] report deals with the hygienic [illegible] Navy and the improvements [illegible] dging of the men in the new [illegible] rator rooms, *and ozonising* [illegible] morning and evening com- [illegible] e current required was less [illegible] It was found that when a stream of air was pumped through a bunker the relative humidity indeed fell from 86·2 per cent. to 45 per cent., but the coal dust that was stirred up made the place more uncomfortable than the heat. A new pattern radiator is [illegible] there will [illegible] e cause of [illegible] ents. The [illegible] ven to the men when necessary, just as extra coal to the engines. It is noted with surprise that fish was never issued officially abroad at meal times. Fruit was not allowed to be bought from bum-boats; only apples, pears, and bananas, *fruits* with skins, were got through the canteen, and these were dropped twice into boiling water for five seconds each time before issue. Water from the shore was almost invariably used for washing only. Wash-basins for the individual men are gradually being provided and in time every man will have his own basin. They are kept either in the man's [illegible]

sumption of beer is decreasi [illegible] on board, and if such drink [illegible] occasions the quantity of [illegible] sale in hot countries. [illegible] give lectures to the [illegible]

the dressing stations. Each has had 14 days' nursing training in the sick bay, and they take the wounded into the operation-dressing room to the doctors, and remove them afterwards to the rest space, and they are skilled enough to look after the very severely wounded there. They are also taught to deal with fire smoke and gas difficulties.

MILITARY SURGEONS IN GERMANY: RECOGNITION OF THEIR POSITION AS OFFICERS.

A correspondent writes: "The jubilee year of the Berlin Society of Army Doctors has been marked in dramatic fashion by the German Emperor as supreme head of the Army. General von Falkenhayn, the Minister for War, attended the meeting and informed the assembled medical men that the Emperor by a stroke of the pen had put an end [illegible] tors of whatever [illegible] o has received a [illegible] commanded by [illegible] y doctors in the same ceremonial fashion as combatant officers are now saluted, and doctors in charge of military hospitals will have disciplinary rights over the men under treatment. Nor is this all. On service they will wear the officer's scarf, and they are to be buried with military honours. This is little short of a revolution, for hitherto the 'health officers' have formed a distinct and subordinate class, however eminent might be the professional services rendered by them to the army of which they form so [illegible] precedence, it is [illegible] perial rescript is [illegible] ofession in its [illegible] ng overdue. It is [illegible] *be the forerunner* [illegible] removal of racial [illegible]

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST (VICTORIA PARK HOSPITAL).—The annual court of governors of this institution was held on March 5th, Sir G Wyatt Truscott, Bt., the treasurer, presiding. It was stated that public support had been received in a degree sufficient to sustain the hospital in full activity during 1913. With regard to the relation of the hospital to the proposed centralised control of measures for the treatment and prevention of tuberculosis, the committee will do all in their power to facilitate the association of the hospital with the general scheme under consideration, while retaining its special and voluntary characteristics. The changes which have already occurred have made it evident that the hospital can best fulfil its functions by an extension of the special departments. With this object the committee have in hand the erection of *buildings for a department for* special chest surgery and also for the most modern methods of dealing with diseases of the heart. Improved accommodation will also be provided for radiographic work. On the advice of King Edward's Hospital Fund the committee are greatly extending the balcony accommodation. These works, involving an expenditure of about £15,000, will very seriously tax the resources of the hospital.

LITERARY INTELLIGENCE.—Messrs. Butterworth and Co announce for early publication the revised and enlarged second edition of "Genito-urinary Diseases and Syphilis," by Edgar G. Ballenger, M.D., professor of genito-urinary diseases, Atlanta Medical College, assisted by Omar F. Elder, M.D., and J. *Edgar Paullin*, M.D – *The Oxford* University Press announce "Plague and Pestilence in Literature and Art," by Dr Raymond Crawfurd, illustrated by a series of 31 reproductions of plague-pictures, principally well-known paintings.—Messrs. Longmans and Co. will issue a *series of monographs* on Physiology, under the editorship of Professor E. H. Starling, F.R.S. The size of the volumes will vary from 100 to 300 pages. The following monographs are in preparation: "The Involuntary Nervous System," by Dr. W. H. Gaskell; "The Physiology of Reflex Action," by Professor C. S. Sherrington; "The Conduction of the Nervous Impulse," by Mr. Keith Lucas; "The *Physiological Basis of the Action of Drugs*," by Dr. H. H. Dale; "The Secretion of Urine," by Professor A. R. Cushny; "The Contraction of Voluntary Muscle," by Dr. W. M. Fletcher; "The Cerebral Mechanisms of Speech," by Dr. F. W. Mott; and "The Chemical Mechanisms of Integration in the Animal Body," by Professor E. H. Starling.

three miles away, so they came and paid fees as private patients. Finally, a woman came with her husband and showed a finger with a suppurating nail. According to the law her husband should have been insured; but "he was not going to be bothered, he meant to pay his way as he went along, and he had neither panel doctor nor insurance book."

All these cases came from the neighbourhood of Wimbledon and Wandsworth, and in these districts of the metropolis it will be seen, therefore, that there is resistance against the Act not merely on the part of medical practitioners, but also on the part of members of the general public, including even very poor people.

(To be continued.)

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LIVERPOOL.

Liverpool Workhouse.

THE Local Government Board has recently issued a memorandum dealing with the old vexed question of the use and condition of the pile of buildings on Brownlow Hill, comprising the main part of the workhouse and Poor-law infirmary of the select vestry. The memorandum states: "The workhouse and infirmary buildings at Brownlow Hill combine together to form a mixed workhouse of an obsolete type in which adequate classification is impossible, and of which the main imperfections may be summarised as arising out of (*a*) an insufficient site, (*b*) a congested and haphazard arrangement of buildings, (*c*) buildings themselves of an antiquated type, (*d*) lack of open ground, (*e*) danger of fire, and (*f*) defects of heating and drainage. We suggest that the number of persons accommodated in the workhouse site at present is much in excess of what is reasonable or hygienic. Thus the workhouse and infirmary is reported to have accommodation for 2511 inmates—viz., 1223 in the workhouse and 1288 in the infirmary. At the date of our visit, however, the total numbers did not exceed 1684." The document proceeds to deal in detail with the various departments. The buildings themselves, with few exceptions, are of an antiquated and unsuitable character. The inadequacy of the accommodation for the sick constitutes the gravest defect of the institution. In the case of the surgical wards for acute cases an improved standard has been attained, not far short of that attainable in modern infirmaries, a result partly due to the comparative newness of the structure and partly due to the greater elevation of the site, but otherwise it may be said without exaggeration that not a single ward comes up to the standard of modern Poor-law infirmary requirements. Many of the wards occupied by lunatics are virtually a series of cellars or basement rooms, which on one side are entirely below the level of the ground and difficult to ventilate properly. A further defect is the lack of adequate yard space outside the buildings. The memorandum continues: "It is only fair to the medical officers of the institution that we should comment on the patient and resourceful manner in which they have contended with the administrative and other difficulties arising out of the defects and shortcomings of the buildings. Owing to the structural character of the sleeping wards and the lack of day-room space it would not be proper to apply to this infirmary the standard of cubic space per bed (600 cubic feet) laid down by the Cubic Space Committee of 1867 for Poor-law infirmaries in the provinces. It is doubtful whether even the metropolitan standard of 1200 cubic feet would be sufficient in all cases." The officers who have made the report agree in thinking that the only true remedy for the conditions now existing is the reconstruction of the institution as an infirmary only, built on modern lines. Irrespective of the land now occupied by the old infirmary, there would be space for buildings at once with three double partitions, each containing about 200 beds, and a smaller partition containing from 50 to 100 beds, with an administration block of sufficient capacity for the whole infirmary when completed. This would give a total of about 1700 beds, in addition to some 150 beds remaining in the present surgical wards, and would leave the existing infirmary blocks for future reconstruction in sections. When ultimately the whole site had been developed as an infirmary the total accommodation would amount to something like 1200 beds. The Local Government Board report and the question of the remedy are to be discussed at a special meeting of the select vestry of the parish of Liverpool.

Death of Mr. Jerome E. O'Sullivan, L.R.C.P. & S. Edin.

Mr. Jerome Eugene O'Sullivan died on March 6th with distressing suddenness at his residence, 37, Shaw-street, Liverpool. He was a native of Cork and was educated at the Queen's College of that city, and afterwards at Edinburgh, where he qualified in 1879. He had been in general practice in Liverpool for over 20 years. In 1907 he was appointed a magistrate for the city. Mr. O'Sullivan was a great opponent of the National Insurance Act. He was president of the local branch of the Non-panel Union, and threw himself wholeheartedly into the fray against the Act, and many of his friends believe that his untimely demise is due in no small measure to the strenuous life he had been leading lately in the campaign against the Act. He was one of the most familiar figures in the profession, remarkable for his fine presence, courtly bearing, and kindly address.

Liverpool School of Tropical Medicine.

At a meeting of the committee of the school held on March 9th it was decided to appoint Dr. B. Blacklock to the directorship of the Runcorn Research Laboratory. This laboratory was established in 1905 for the purpose of working up the material brought back by the various scientific expeditions which have been dispatched by the school from time to time to the tropics. The rapid accumulation of material and the scientific papers published by workers in the laboratory have made it an important centre for research in tropical medicine, while the collection of living trypanosomes and other parasites causing fatal disease in man and domestic stock in the tropics, maintained at Runcorn for teaching and research purposes, is one of the largest in the world. Dr. Blacklock has had great experience of tropical diseases both in Africa, where he has spent three years, and in this country.

March 10th.

WALES AND WESTERN COUNTIES.

Housing in Newport.

THE population of Newport, Mon., is now approaching 100,000, and has increased during the ten years ending 1911 by nearly 25 per cent. The proximity to the seaboard on the one hand and to the coal-fields on the other is attracting many new industries to the town; one large undertaking about to be established will employ some 3000 men, and other smaller enterprises are being organised. Already 3500 houses in the town are occupied by more than one family, and of the 15,000 houses in the borough only 133 were unoccupied at the end of 1913. In these circumstances the corporation has decided to erect 100 dwellings under the provisions of Part III. of the Housing of the Working Classes Act, 1890, and the medical officer of health, Dr. J. Howard-Jones, is urging the preparation of a town planning scheme which would have to be on a site or sites beyond the boundaries of the borough. At a housing conference of delegates from local authorities in South Wales, Monmouthshire, and Herefordshire, held at Newport on Feb. 26th, the Mayor of Newport suggested that the funds of the Miners' Federation and of the railway workers' organisations might with advantage be used in the promotion of housing schemes. Mr. H. R. Aldridge, secretary of the National Housing and Town Planning Council, urged that the funds of the Post Office Savings Bank might be used for housing purposes, in which case a lower rate of interest would be paid by local authorities who erected houses.

Conditions affecting a High Birth-rate.

At the last meeting of the West of England and South Wales Branch of the Society of Medical Officers of Health held at Swansea, there was a discussion upon the influence of housing conditions and of the ingestion of lead on the limitation of families. Dr. T. E. Francis, medical officer of health of Llanelly, pointed out that where good sanitary conditions prevailed families were small, and he quoted in support of this contention the fact that the birth-rate was much higher in rural than in urban districts. He had found that in Llanelly the ward with the lowest birth-rate had the smallest proportion of tenements rated under £10 per annum, and that in the ward with the largest proportion, 78 per cent., of small tenements the birth-rate was the highest. Dr. J. D. Jenkins, medical officer of health of the Rhondda urban district, considered that overcrowding of houses influenced the birth-rate not in the direction of the limitation of families, but rather in the direction of the increase in the birth-rate by promoting early marriages and by tending to increase the number of illegitimate births. He also agreed that there was some justification for attributing the diminished and diminishing birth-rate in the Rhondda valleys to improved and better housing conditions. On the question as to whether lead poisoning affected the birth-rate, he compared two districts in the Rhondda valleys, one of which is supplied with water having plumbo-solvent qualities and the other devoid of such qualities. In the former area there have been many pronounced cases of lead poisoning, and in the ten years 1903–12 the birth-rate was 37 per 1000, compared with 39·4 per 1000 in the other area. During the first half of the decennium the difference in the two areas was 3·2 per 1000, and in the second half only 1·3 per 1000, and it was during the second half that special measures were taken to remove the plumbo-solvency of the water. Dr. Thomas Evans, medical officer of health of Swansea, was of opinion that the birth-rate was kept up by overcrowding. He considered that when the family of a working man increased and he had to move to a larger house his rental should not be raised.

The "Mortuary" at Princetown.

At an inquest recently held at Princetown (Devon) the medical man who performed the necropsy complained of the "mortuary," which, he said, was an absolute disgrace, being only a little tin-covered building with no window, no place to hang a coat or to wash the hands, with the door wide open to the public thoroughfare. People looked in out of morbid curiosity. The coroner remarked that it was a scandal and said he would communicate with the parish council.

Shortage of Midwives in Devon.

At the meeting of the Devonshire Nursing Association held on Feb. 27th the county medical officer of health, Mr. G. Adkins, drew attention to the shortage of trained midwives in Devonshire. Mr. Adkins stated that there were 200 untrained midwives in the county and only about six of these carried out the rules of the Central Midwives Board. The condition was really appalling, but the Public Health Committee had sent the names of many of these women to the Central Midwives Board, and they had all been removed from the roll, and a like course would be followed in the case of others.

Bristol Medical Dramatic Club.

The Bristol Medical Dramatic Club recently gave their thirty-sixth annual performance, when *The Upper Crust* was played on five occasions at All Saints Hall, Clifton, the performances being given in aid of the Bristol Eye Hospital. The comedy was ably rendered to a large and appreciative audience.

The late Dr. John Ernest Paul.

The funeral of the late Dr. J. E. Paul took place at Torquay on Feb. 17th, and was largely attended by the local members of the medical profession. Dr. Paul, who received his medical education at University College Hospital, London, qualified L.R.C.P. Lond. and M.R.C.S. Eng. in 1890, and graduated M.D. Lond. in 1892. After holding resident appointments at University College Hospital Dr. Paul settled in Torquay, where he became honorary physician to the Western Hospital for Consumption, Erith House, Rosehill Children's Hospital, &c. Dr. Paul was highly respected, and he will be much missed in Torquay.

March 10th.

IRELAND.

The Royal Colleges and the Working of the National Insurance Act.

LAST autumn complaints were made to the two Royal Colleges of Ireland as to alleged unprofessional conduct of certain Licentiates of the Colleges in the carrying out of the duties of the offices which they had accepted under the National Insurance Act. It was alleged that in the course of examining members of Approved Societies who were claiming sickness benefit some medical advisers or referees had not only visited patients under the care of other practitioners without the knowledge of the latter, but had commented adversely on the treatment given. The Colleges have so far postponed investigations of specific complaints, but have thought it wise to suggest rules of conduct by following which friction might be avoided. A joint committee of the Colleges was appointed, which after long deliberation made certain recommendations. The Colleges have now expressed their views in the following unanimous resolutions, which have been promulgated to the several Fellows, Members, and Licentiates.

Resolved—

That in the opinion of the Royal Colleges of Physicians and Surgeons, Ireland, the existing arrangements for obtaining evidence of incapacity, entitling to benefit under the National Insurance (1911) Act, have given rise to serious abuses.

In forming a judgment as to whether a person is "incapable of work" it is essential, alike in the interests of the public and of the claimant, that the fullest possible information as to the medical condition of the claimant should be before the person whose duty it is to adjudicate on the claim. This information is, as a rule, in the possession only of the claimant's medical attendant.

The Colleges are of opinion that medical certificates under the Insurance Act should be accepted only if given by the claimant's medical attendant, if any, unless such medical attendant refuses to certify.

If the Body claimed against desires to review a certificate, the Colleges are of opinion that the medical referee should have before him the certificate originally given by the claimant's medical attendant, and should give such medical attendant sufficient notice of the time and place of examination, and an opportunity of stating the grounds on which he arrived at the opinion expressed in his certificate.

Resolved—

That the manner in which the duties of the office of "medical adviser," either to the Insurance Commissioners or Approved Societies, are being discharged at present in many parts of Ireland is contrary to medical ethics, and deserving of punishment by the Colleges.

In thus warning their Licentiates of the danger they may run the Colleges have rightly interpreted their function of preserving the interests of the public and safeguarding the honour of the profession. They have shown, too, that they are more anxious to guide medical men in the right way than to punish those who, perhaps from lack of forethought, have erred. This expression of opinion by the two Colleges must have weight with the authorities in considering the future working of the Act.

A Radium Institute for Dublin.

The Royal Dublin Society is taking steps to establish a radium institute in Dublin, Lord Iveagh having contributed £1000 towards the cost of the purchase of additional radium. It is hoped that radium treatment may be made available both for hospital and private patients under convenient conditions.

Health of Belfast.

At a meeting of the city council of Belfast held on March 2nd the report submitted as to the health of Belfast between Jan. 18th and Feb. 14th showed that 262 cases of infectious disease had been notified, including 192 of scarlet fever, as compared with 288 in the previous four weeks, and only 150 in the corresponding period of 1913. The total death-rate from all causes was very high—22·4 per 1000, as well as that from chest affections—9·0 per 1000, while the death-rate from zymotic diseases was 1·5.—A delay has arisen in entering upon the practical work of the tuberculosis scheme of the corporation owing to some hitch in regard to the transference by the board of guardians of the Abbey Sanatorium to the Belfast city council. The corporation blames the board of guardians while the latter in reply say they are not in any way responsible for the delay that has taken place, which "had been occasioned entirely by the corporation and its officials." The Local Government Board will have to settle the matter.

Dispensary Doctors' Salaries.

The finance committee of the Belfast board of guardians has agreed to recommend that the salaries of the dispensary doctors in the Belfast union, as well as all the visiting medical officers of the workhouse, shall be increased. The report is to be considered at a further meeting of the board of guardians.

Ulster Medical Society.

On the evening of March 5th the President of the Ulster Medical Society (Mr. A. B. Mitchell) and Mrs. Mitchell gave a most enjoyable "At Home" in the Medical Institute, Belfast, to the Fellows and members of the Ulster Medical Society and their wives. The lecture-room of the institute was furnished as a drawing-room, and here Mr. and Mrs. Mitchell received their guests. An admirable programme of vocal and instrumental music by the "Beethoven House Orchestra" was provided during the evening, while Mr. M. Davies also gave some selections, which were much appreciated. Refreshments were provided in the library and there were card tables in the billiard room. The evening passed off most successfully and was greatly enjoyed by the very large company who were present.

March 10th.

BUDAPEST.

Trials of Friedmann's Anti-tuberculous Treatment in the Budapest Clinics.

INDUCED by the favourable results which were reported last October in Germany by Dr. Schleich, Dr. Müller, Dr. Thalheim, Dr. Immelmann, and Dr. Kraus, after they had given a fair trial to Dr. Friedmann's treatment, the medical staff of some Budapest hospitals resolved to employ it in their wards. On Dec. 2nd and 3rd Dr. Friedmann himself performed inoculations in the St. Stephen and the St. Rochus Hospitals, both of which supply clinical material for the purpose of medical education. The President of the Interhospital Medical Society has invited Dr. Havas, professor of dermatology, to exhibit 14 cases of tuberculous disease of the skin which are under his care, and have been treated by Friedmann's remedy. The inoculations were made early in February of this year; the cases were shown in the untreated state, and they will be shown again in from eight to ten weeks, when their treatment will be finished.

A New Method of Treating Warts.

Dr. Felix Szontagh, of Budapest, recommends a new and simple method of treating warts. It consists in covering the wart and the surrounding skin, to the width of 1 centimetre, with ordinary caoutchouc plaster, and leaving it so covered for weeks—even, if necessary, for two or three months. Whenever the plaster becomes loose it must be removed and replaced by a new piece. As a rule the plaster is to be changed once in three or four days. Any adherent residue of the caoutchouc is to be removed with ether or petrol, care being taken that the wart or the surrounding skin shall not be rubbed energetically, because irritation of the skin is not conducive to the disappearing of the wart. Dr. Szontagh says that he cannot explain the action of this simple method and how it produces such excellent results from the cosmetic point of view, but it is certainly efficient. Perhaps the caoutchouc contains some substance which softens the wart and causes atrophy.

Proposed Neutrality of Balneary Centres and Health Resorts in Case of War.

The *Magyar Balneologiai Ertesitö (Hungarian Balneological Journal)* publishes an article by Professor Kisch, one of the greatest balneological experts in Austria. I see that your Berlin correspondent has briefly alluded to the communication. It was originally sent to Professor Arpád Bokay, president of the Hungarian Balneological Society, with the request that if Dr. Bokay approved of the proposal he would approach the Ministry of Foreign Affairs in support of it. Professor Kisch had already written on the subject in 1866, when military operations were taking place in the immediate vicinity of the world-renowned Bohemian balneary towns, Carlsbad, Marienbad, and Franzensbad. One year later the question was brought before the Bohemian legislature in the form of an interpellation, and then the Governor asserted that he sympathised with the idea, but that the question could only be settled by joint international action. In 1896, at the International Congress of Associations for the Nursing of the Wounded, Professor Langenbeck, the head of the medical department of the Prussian army, proposed that the Congress should communicate to the governments of the different countries its opinion that in case of war all health resorts should be declared neutral, and should be utilised for the accommodation of sick and wounded soldiers. During the long peace which followed the Congress the matter was in abeyance, but now, when rumours that peace is likely to be broken are frequent, the question has been revived, and Professor Kisch thinks that it would be worth while to consider the matter again. Of course, an extension of the Geneva Convention would be absolutely necessary. If this could be done it would be a great advantage to sick and wounded soldiers, because in the Austrian balneary towns alone there are about 100,000 beds, at least the half of which could be occupied by soldiers. The health resorts would not lose by this arrangement, because the cost of the soldiers' food and housing would be repaid by the State, and thus a good part of the loss suffered by the proprietors on account of the war would be compensated. Dr. Kisch says that all unions and societies formed for the purpose of nursing sick and wounded soldiers ought to unite with the Hungari

BERLIN.

Decrease of the Birth-rate.

THE constant decrease in the birth-rate in Germany has for some years past created considerable uneasiness in both political and medical circles. The causes of this are not yet very clearly ascertained, and a variety of opinions have been expressed regarding it. Some authorities consider that the birth-rate depends only on economical reasons; it is alleged that the protective tariff, which has increased household and personal expenditure in this country, has induced the working-class population to limit the number of their children because they are unable to bring up large families. Others say that the decrease in the number of children is a sign of culture; in nations of a high cultural standard—as, for instance, in France—the average number of children is small, whilst in nations of a lower standard, such as Russia, there is no intentional limitation of the number of children in a family. Moralists complain that the increase of luxury, especially among the upper classes, has the effect of inducing women to abstain from having children, who are regarded as a burden. It is moreover stated that of late years the sale of anticonceptional appliances in Germany has become an actual scandal. These things were formerly almost unknown among the peasantry and the working population, and were used only by the well-to-do classes. Nowadays agents sent by the manufacturers of these articles visit the homes of the working classes both in town and country and induce them to buy these appliances at extremely high prices. At the entrance gates of factories, collieries, and mines persons are employed to distribute pamphlets containing warnings against producing too many children owing to the expenses connected with them. Legislative measures are therefore believed to be necessary for the repression of those evils, and the Roman Catholic party in Parliament has now brought forward a Bill for that purpose. According to the terms of the Bill the Federal Council is to be empowered to limit or prohibit altogether the sale of anticonceptional drugs and appliances, as far as they are not at the same time useful to prevent venereal infection. The importation of these drugs or instruments from abroad is also to be prohibited, and when they have been imported the Federal Council shall have the right to seize them even if the importer is not under German jurisdiction. The advertisement of such drugs and instruments is to be made a criminal offence, punishable by a fine not exceeding 1500 marks, or by imprisonment for six months. Exception is made in the case of medical and pharmaceutical journals. The Bill is at present under discussion in a committee of the Reichstag. The majority of the press is opposed to it, and a number of Professors of the University of Berlin have been asked their opinion by a leading newspaper of that city. Nearly all of them have declared that the proposal is open to the objection that a considerable number of instruments and pharmaceutical preparations used for the prevention of conception are also used as safeguards against venereal infection, and to prohibit the sale of them would result in an increase of venereal diseases. Gonorrhœa being a well-known cause of sterility, any increase of that disease would tend to depress the birth-rate, so that an effect contrary to that desired by the promoters of the Bill would eventually be produced. The anticonceptional preparations and appliances would continue to be sold at an advance over the present prices owing to the sellers being liable to punishment. It is certainly true that so complicated a question as the decrease of the birth-rate cannot be solved by police measures, and the Bill, which will inevitably interfere with the personal rights of individuals, may be dropped.

Health of the French and German Armies.

According to the French newspapers the health of the French army, especially in the garrisons near the eastern frontier, is by no means good owing to the existing barrack accommodation being unable to meet the extra demands made on it in connexion with the recent sudden increase of the army. These newspapers, moreover, assert that measles, scarlet fever, influenza, and cerebro-spinal meningitis are prevalent in those garrisons. In January, when the number of the French army was 717,415 men, 44,192 had been treated in the sick rooms of barracks and 21,570 in the military hospitals, of whom 280 died. As some French journals have published statements to the effect that a similar unsatisfactory state of affairs existed in the German army, the Minister of War was asked in Parliament whether the reports were true or not. He answered that in January, when the number of the German army was 771,100, there were 20,044 men who had been treated in the sick-rooms of barracks and 18,610 in hospitals, the number of deaths having been 113, including accidents and suicide. This is all the more satisfactory as the recruits numbered 60,000 more than in former years, and it is remarkable that of the recruits who came to the army last autumn only 4 per cent. had up to Feb. 1st been discharged on account of illness.

Death of Professor Joachimsthal.

The early death of Dr. Joachimsthal, professor of orthopædic surgery and director of the orthopædic clinic in the University of Berlin, is much regretted. He was born at Stargard in Pomerania in 1863, and studied medicine at the University of Berlin. Having passed the State examination he became an assistant in the orthopædic clinic under Professor Julius Wolff, who was well known by his important researches on the structure of bone. In 1898 Dr. Joachimsthal was recognised as *privat-docent*, and in 1902 he was appointed professor. In 1908 he became the successor of Professor Hoffa as director of the orthopædic clinic, and held this appointment until his death, which was due to an apoplectic seizure. His work was concerned almost exclusively with orthopædic subjects, and his essay on functional alterations in the form of the muscles was "crowned" by the Academy of Sciences in Paris. His great treatise on orthopædic surgery has become a standard work in Germany. With the late Professor Hoffa he was the co-editor of the *Zeitschrift für Orthopädische Chirurgie*, and after the death of Professor Hoffa he was the only editor of that journal, for which he wrote numerous articles on different subjects. He was the permanent secretary at, and several times the president of, the Congress of Orthopædic Surgery. His amiable and unassuming disposition endeared him to his professional brethren, so that his death is universally mourned.

March 9th.

ROYAL WEST OF ENGLAND SANATORIUM, WESTON-SUPER-MARE.—The annual meeting of the subscribers of the Royal West of England Sanatorium was held on Feb. 21st. The medical report showed that during 1913 1472 male and 1133 female patients were admitted; of this number 952 had been cured, 905 much improved, and 537 improved. 9000 warm sea-baths had been given during the year under trained supervision and had been much appreciated. The financial statement showed that the income amounted to £4897, and had the claim for refundment of income-tax, about £40, been met before the closing of the accounts, there would have been a small favourable balance in hand. During the past year the electric light has been installed in the sanatorium, at an expenditure of over £1000. The whole of this sum has been raised by the efforts of the lady superintendent, Miss Mawe.

Obituary.

ROSWELL PARK, M.D., LL.D.,

PROFESSOR OF SURGERY, UNIVERSITY OF BUFFALO.

THE distinguished American surgeon, Dr. Roswell Park, died at Buffalo on Feb. 15th at the comparatively early age of 62.

Roswell Park was born in Pomfret, Connecticut, in 1852. His father was a clergyman. Both his father and mother were descended from distinguished American families. An ancestor, Colonel James Baldwin, was a member of the staff of General Washington, and was present in that capacity at the crossing of the Delaware. Dr. Park was educated at Racine College, Wisconsin, which was founded by his father, where he graduated in arts in 1872. He studied medicine in the North-western University, Chicago, and after graduating spent two and a half years as an interne in two of the largest hospitals in Chicago. When only 25 years of age Dr. Park began his career as a teacher. At first he was demonstrator in anatomy in the Woman's Medical College of Chicago. He was next made assistant professor of anatomy in the Chicago Medical College. After studying in Europe, chiefly in Vienna, for a year, he was appointed lecturer on surgery in Rush Medical College, Chicago. In 1883 he was appointed professor of surgery at the University of Buffalo, New York, which he held up to the time of his death.

Dr. Park was a many-sided man. He was cultured, musical, and one of the best writers of English among the medical men of the United States. He wrote the Mather Lectures on Surgery, an Epitome of the History of Medicine, a "Practice of Surgery," and edited the serial work, "Surgery by American Authors." He was the author also of several essays. Dr. Park received the honorary degrees of LL.D. from Yale University, of M.A. from Harvard University, and of M.D. from Lake Forest University. He had been President both of the American Surgical Association and of the Medical Society of the State of New York. He held a non-resident professorship in the Army Medical School, Washington, and was a visitor to the West Point Military Academy.

When President William McKinley was shot at the Pan-American Exposition in Buffalo in 1901 Dr. Park was with the wounded President to the end, but he was best known for his researches on cancer, and it was wholly by his instrumentality that the New York State Cancer Laboratory, known as the Gratwick Laboratory, of which he was the Director, was established in Buffalo. Dr. Park was a popular man, of a gentle, tender, and generous nature. He numbered his friends by hundreds throughout the English-speaking world.

FRANCIS VACHER, F.R.C.S. EDIN., M.R.C.P. EDIN., J.P.,

CONSULTING SURGEON TO THE WIRRAL HOSPITAL FOR CHILDREN.

WE regret to announce the death of Mr. Francis Vacher, which took place at Port Said on Feb. 25th.

Mr. Vacher, who was the son of Mr. Thomas Brittain Vacher, was born at Brompton, London, on Feb. 13th, 1843, and therefore had just entered his 72nd year when he died. He was educated privately, and having a penchant for art, studied along lines which his bias suggested at Kensington and in Germany. Later, however, he turned his attention to medicine, and at the age of 21 went to Edinburgh and took the double qualification of the Royal Colleges. He was a student at the university, but did not graduate in medicine. In 1866 he was appointed house surgeon at the Royal Maternity Hospital, Edinburgh, and a year after he took a similar post at the borough hospital in Birkenhead.

In 1873 he was appointed medical officer of health and public analyst to Birkenhead, and it was in this year that his early midwifery experience led him to invent a pair of forceps which he described in the Liverpool and Manchester Medical and Surgical Reports. He took the F.R.C.S. of Edinburgh in 1878 and the M.R.C.P. in 1882. In 1893 he was appointed medical officer of health and later medical inspector of school children for Cheshire, which post he resigned four years ago. Mr. Vacher made many contributions to medical literature, including a paper on the use of "Blood Serum as a Therapeutic" in 1876; "Notes on the Epidemic of Small-pox at Birkenhead in 1877"; and a paper on Exanthemata and some Allied Diseases, in which he dealt with the duration of the latent period. His contributions on public health included "The Food Inspector's Handbook" (1892), "A Healthy Home" (1894), and many others, among them being "Public Baths," "Defects in Plumbing and Drainage Work," and "The Dead Body as a Source of Infection." He was also the author of "Seduction in Edinburgh." Mr. Vacher was a Freeman of the City of London, a Past Master of the Tallow Chandlers' Company, and a member of the Court of Assistants. It is interesting to note that this old city company, whose foundation dates back to the early part of the fifteenth century, had powers to search for and destroy all bad and adulterated oils, and no member of the company was allowed to mix "deceitful" tallow with the best tallow.

Mr. Vacher was one of the founders of the Birkenhead Medical Society and had been President. He had also been President of the Incorporated Society of Medical Officers of Health. He was made a justice of the peace for the Wirral Division in 1910. He was a Fellow of the Royal Sanitary Institute, a Fellow of the Chemical Society, and a member of the Société Française d'Hygiène.

Mr. Vacher, who had recently been in indifferent health, decided to take a voyage to the Holy Land with his wife, a daughter of the Rev. John Mollan Bleckley, whom he married in 1899, and his two daughters. He left England on Feb. 13th, by a coincidence his birthday, but caught a chill during the voyage, and, as already stated, died at Port Said, where he was buried.

EDWARD DORSET FARMAR BRINGHURST,

F.R.C.S. EDIN., F.R.G.S.,

MAJOR A.M.S (RETIRED).

BY the death of Major Farmar Bringhurst, which took place on Jan. 30th at St. George's Hospital, after an operation, an interesting and varied career was brought to a close. Born in 1854, Major Bringhurst was the eldest son of the late Lieutenant-Colonel W. M. Farmar, of Bournemouth. He received his medical education at St. George's Hospital, at the University of Edinburgh, and at Paris. He qualified by becoming L.R.C.P. Edin., L.R.C.S. Edin., and L.M., in 1877, proceeding to the F.R.C.S. Edin. in 1880. In the year in which he qualified he was appointed medical officer to a party of seven persons who visited Australia on behalf of the Government of Victoria to report as to the possibility of building a canal from Melbourne to Hobson's Bay, and after visiting the Gold Diggings, Tasmania, and New Zealand, he returned to England. Later he went to India, and subsequently in 1881 joined the Army Medical Service as a surgeon.

In 1882 he volunteered for active service in Egypt, in the Arabi rebellion, and after the bombardment of Alexandria was attached to the cavalry brigade at Ismailia under Lord Wolseley and H.R.H. the Duke of Connaught. For his services he received the Egyptian medal and the Khedive's Star. In 1883 he went to South Africa for five years, serving in Capetown, Natal, and Zululand. In 1888 he was appointed to the charge of a field hospital in Zululand, was present at the operations against Dinizulu, and saw the last shot fired in connexion with the closing scene of the Zulu rebellion. In 1889 he went to India, where he served for several years. In 1891 he was appointed to the medical charge of Bhamo, on the Chinese frontier. Later he was placed in charge of Shwebo, and received the thanks of Brigadier-General G. B. Wolseley, C.B., for his care of the sick and wounded from the Wuntho column, after the operations against the Swabwa of Wuntho. In 1895 he served on the Malabar coast of India, and organised the medical arrangements for British troops sent from Wellington to the Nilgiris, against the Moplahs in the Malapuram district. He returned to England in 1896, and was stationed at York headquarters as company officer, retiring from the army in 1898. He was elected a Fellow of the Royal Geographical Society in 1899, having, in the previous 20 years, travelled more than 200,000 miles over ocean and land—roughly about eight times the distance round the world.

ROYAL DEVON AND EXETER HOSPITAL.—The annual meeting of the governors of the Royal Devon and Exeter Hospital was held on Feb. 26th. The medical report stated that during 1913 the in-patients admitted were 1680, and 3957 out-patients were treated, as compared with 1754 in-patients and 5033 out-patients in 1912. The daily average number of occupied beds was 152, the average stay 33 days, and the cost per occupied bed £65 13*s.* 5*d.* The financial statement showed that the ordinary receipts amounted to £10,687, and the excess of ordinary expenditure over ordinary income amounted to £1654. It was decided to initiate a throat, nose, and ear department, and the necessary rooms will be fitted up in the out-patient department.

EDGAR ALLEN INSTITUTE.—Reference has been made in recent years in these columns to the Edgar Allen Institute for Medico-mechanical Treatment, 77, Gell-street, Glossop-road, Sheffield. The committee now announce that unless they [illegible] financial assistance t[illegible] it will be compelled [illegible]xt. The institute was founded chiefly for the benefit of the wage-earning classes, and with the view also of introducing into this country the Zander method of treatment, which has been successfully practised on the Continent for many years. The building and the equipment were the gift of Mr. W. Edgar Allen to the city, and he also held himself responsible for the cost of upkeep during the first three years of its existence. Up to Dec. 30th last 1388 patients, chiefly from the working classes, were admitted. The expenditure is about £1600 per annum, towards which certain fees, amounting to about £700, are received. The institute is under the immediate care of a medical director, Dr. R. G. Abercrombie, with a trained Swedish staff, and patients are received for treatment only upon the introduction of a medical man.

Correspondence.

"Audi alteram partem."

SYPHILIS AND "MENTAL DEFICIENCY."

To the Editor of THE LANCET.

SIR,—The recent appointment of the Royal Commission on Venereal Diseases and the passing of the Mental Deficiency Act have stirred up public interest in these subjects, and it is no matter for surprise that any evidence tendered regarding a causal connexion between syphilis and mental defect should attract popular notice. Many persons interested in these matters are likely to accept inferences drawn from imperfect and unchecked observations as scientifically established conclusions. I have lately heard more than one person of prominent position make the assumption that mental deficiency has been proved to be chiefly caused by syphilis, either congenital or acquired; and that the problem of the etiology of mental defect had thus been approximately, if not wholly, solved! It is not my purpose to discuss the question of the rôle of syphilis in causing certain cases of mental defect, or of the Wassermann process being a scientifically established test for the presence or absence of the syphilitic virus. I desire rather to call attention to the necessity for exercising the greatest caution both in the observation of facts and in the method of interpreting them before making public any doctrine or implication that syphilis is a predominant cause of mental defect generally.

It is now widely known beyond medical circles that the Wassermann test has led to the discovery of the probable existence of the syphilitic virus in many cases which show no clinical signs of syphilis, the *disease;* and that, as a consequence, the pathogenic field of syphilis tends to become rapidly enlarged. In fact, at the present moment, the etiological question of the relation of syphilis to mental deficiency generally seems to turn almost wholly on the proper use and valuation of the Wassermann test, and on the proper use of the scientific method in endeavouring to ascertain how far syphilis may rightly be regarded as a causative factor in the production of mental defect in cases thus tested which show a positive reaction. For it must be remembered that, apart from this test, which is believed frequently to reveal unsuspected syphilis, and apart from its promiscuous application at the present time to large numbers of mentally defective cases, many of which are admitted to be of very slight degree, the actually wide question now under consideration would not have arisen.

More or less recently published records of cases where the Wassermann test has been applied to idiotic, imbecile, and many other "mentally defective" children show highly varying results as to the frequency of a positive reaction, this variety being probably due to dissimilarities between cases examined, methods used, and persons observing, as well as to other conditions. A record of two groups of mentally defective children thus examined by Dr. K. Fraser and Dr. H. F. Watson was published in the *Journal of Mental Science* for October, 1913, showing that a little over 46 per cent. of all these cases gave a positive reaction. One group of cases, numbering 89, consisted mainly of "defective" children attending "special schools"; the other, numbering 105, of out-patients at the Royal Hospital for Sick Children, both in Glasgow. Only slightly over 16 per cent. of these cases showed *clinical* signs, or "stigmata," of syphilis. It is also stated in this report that about the same proportion of positive reactions was found in epileptic children *without mental defect.* The chief conclusions drawn by these writers from their joint observations as a whole are (1) that "syphilis is *the causative* factor in a very considerable percentage of cases of mental deficiency of whatever degree of severity, as it is present in over 50 per cent."; and (2) that "syphilis is also the main *causative* factor in the production of that type of epilepsy which manifests itself at early ages." It is necessary to comment now only on the first of these conclusions.

That this conclusion is wholly unwarranted by the facts adduced needs no detailed demonstration. Granting the accuracy of the test and the facts generally, nothing is shown but that in about half of the cases examined some degree of mental defect co-existed with evidence of the presence of the syphilitic virus. In the other half of the cases examined the test was mainly "negative," but in a few "doubtful." It is true that Dr. Fraser examined 23 "normal" children as "controls," and finding that 19 gave a "negative," 2 a "positive," and 2 a "doubtful" result, regarded this observation as "significant," in spite of the smallness of the number examined. But it is clear that this number is far too small to be of any value in lending support to the conclusion arrived at, that syphilis is *the causative* factor of at least half the cases of mental defect in children; and it must be remembered that 8 per cent. of the *normal* "controls" showed a *positive* reaction. It is surely necessary, before even entering into any discussion of a causal connexion between syphilis as evidenced by the Wassermann test and mental defect generally, to ascertain the frequency of the positive reaction in large numbers of children of similar status and condition who, by common consent, can be classified as of good or average mental capacity. And it is equally clear that, whatever might be the result of this preliminary observation, the inquiry into the validity of this particular hypothesis of the causation of "mental defect," in the wide sense of this term employed by the writers, would not, from the point of view of scientific method, be far advanced, but only just beginning.

It has been said above that there are very great discrepancies between the results obtained by many different observers who have applied the Wassermann test to cases of "mental defect." We have seen that Dr. Fraser and Dr. Watson claim very positively that they have *proved* more than the concomitance of syphilis and mental defect in over half of the 194 cases examined. They assert that the one is the *cause* of the other. With their result must be contrasted that of an inquiry (referred to by themselves) which was based on the examination of 2061 cases of mental defect by *four* observers.[1] This research showed a percentage of only 1·5 cases with a positive reaction to the test.

Even assuming that the Wassermann process may be regarded as an absolutely scientific test for the presence of syphilitic infection, it is clear that at present no positive conclusions as to the relations of mental defect to syphilis can be drawn from any accounts hitherto published. Further, there has been hitherto, as far as I am aware, no attempt made to ascertain the frequency of positive reaction to the test in the blood of large numbers of individuals of similar conditions to those composing the special groups under investigation, but to whom "mental defect" cannot be attributed.

---

[1] See Berliner Klinische Wochenschrift, 1911, xlviii., p. 891.

And with regard to the Wassermann test itself, especially in view of the wide-reaching and important conclusions which are now being positively drawn from its results, it must be remembered *that experience has shown, and is showing, the great* frequency of disagreement between observers concerning the facts observed. Cases have occurred where the same blood has been examined by three different experts in hæmatology, with the respective results of "positive," "negative," and "doubtful"; and it is known that the issue of the observation is often doubtful when the individual is under treatment. In relation to any question respecting the pathogenic action of syphilis, and notably in cases where practical and public interest and action may be concerned, there is clearly great reason to pause before accepting the facts and, by consequence, the inferences of those who promulgate practical doctrine on the strength of their use of the Wassermann process alone.

I am, Sir, yours faithfully,

March 7th, 1914. H. BRYAN DONKIN.

⁂ In connexion with Sir Bryan Donkin's valuable and suggestive letter we refer readers to the prefatory statements in Dr. Carl Browning's description of the technique of the Wassermann reaction, published in this issue of THE LANCET. Dr. Browning points out that "the limit of reacting power which differentiates a positive serum from a negative one must be arbitrary, and requires to be fixed by experiment for any given combination of 'antigen' and serum."—ED. L.

THE TREATMENT OF INCIPIENT AND UNCONFIRMED INSANITY.

To the Editor of THE LANCET.

SIR,—Your excellent leading article on this subject voiced a spirit of caution, and I venture to think that you expressed the feeling which many who have had much experience in lunacy administration hold. If it is a fact that the dread of lunacy certificates prevents the early treatment of acute mental disease, then by all means do away with them if possible. But is it a fact? Are people now prevented from being properly treated through the fear that if so treated they will be certified? To some extent this seems undoubtedly true. The *objection* of the public to certificates of insanity is easy to understand, and in its way this hesitation is useful because it tends to retard the premature interference with the liberty of the patient; but my experience is that where the danger of delay is fully explained to the friends, the difficulty of getting them to see the necessity for certification disappears.

Certificates are framed primarily for the protection of the patient, though at times the safety of the public and the interests of the family may be the primary factors; and I have often found that this question of "slur and stigma" depends largely upon the attitude of the patient towards his friends, for the moment he becomes troublesome or threatening or inclined to squander money all the qualms about "stigma" suddenly disappear and are replaced by urgent clamours for the protection afforded by certificates. What really frightens the friends is the word "insanity," not the mere certificates, but the idea that there is brain disease in the family, and they use all sorts of subterfuges for putting others off the scent. The patient is either "neurotic," or "neurasthenic," or "hysterical," or has "had a nervous breakdown," or he has "brain fever," anything to save the word "insanity," and the dread of certificates and registration is mainly due to the fear that by these processes the fact of insanity in the family will become widely known. Of course, certificates are the official cachet of the fact that insanity exists, and this may be one reason why the friends are so opposed to them, and much as they dislike the idea of insanity in the family they dislike still more the official stamp of it.

Have we *in the course of medical progress* arrived at the time when there is less need for certificates? Are the conditions of to-day so much more favourable for the treatment and the safety of the patient that certificates are less necessary than formerly? If so, I confess that I see no outward sign of it. Only last year on urgent medical and lay representation a new Act was passed to include under compulsory restraint many who it appears cannot even now be entrusted to the care of their friends, and powers are given in this new Bill to provide new institutions and officials to work them! The Board of Lunacy Commissioners has been increased and new duties of supervision thrown upon it. Does this look as if the late methods erred on the side of stringency? Does Dr. Armstrong-Jones suggest that any considerable number of the certified acute mental cases under his care could, with advantage to themselves, be released from their certificates and might dispense with the inquisitorial care of the Commissioners, and does he look forward to a time when the powers of the latter will be less needed?

Dr. Armstrong-Jones uses very forcible expressions about "slur and stigma," but it must be supposed that he is guided in his remarks by hearsay evidence, because his patients are *already certified* when they come under his care, and so (I hope it will not be thought irrelevant of me to say it) he has not the opportunity of seeing the very early cases whose treatment without certification he earnestly advocates. Do the friends of the patients under Dr. Armstrong-Jones's care express to him their objection to the mere fact of certificates, or is it that what they really object to is the detention in an "asylum," and *is it probable that their objections* would disappear if the patients were in a "mental hospital" or "home" without certificates or supervision? The friends of patients who are in institutions under certificates ought to know that they can always remove them on giving guarantee of responsibility. How often do they do this? Medical men in private practice know that the proposal to certify a patient is generally coldly received, and there is no doubt that *in the doctor's desire to meet* the friends' wishes many patients are allowed to be at large who would be better placed under certified care, and one result of this is that "accidents" happen. I believe that medical men have the greatest objection to signing certificates, looking upon them as indicative of the failure of treatment, just as a good surgeon shuns operating if he can possibly help it, and views it as the last resource in the interest of the patient, *all other treatment* failing. The question now arises whether the friends of patients ought to be allowed to enforce their objections to certification when treatment cannot be adequately carried on at home. In the case of infectious disease there must be notification, and, *nolens volens*, the patient is promptly carried off to a special hospital, and though it cannot be suggested that private cases of incipient insanity should be notified, it does not seem undesirable that if a patient is in a state fraught with danger to his mental integrity he should be denied proper treatment because of a sentimental objection to his being safeguarded! There are, in fact, cases where the measures which are freely allowed in infectious disease should be extended to mental conditions when these assume symptoms of a force dangerous to the patient or the community, and it is open to doubt if mental hospitals can be successfully carried on without some means of detaining the patient if he refuses to stay, for it is notorious that the voluntary boarder system breaks down in the very cases where one desires most to try it. The patient simply will not sign the request for admission, though knowing that he can voluntarily leave at a few hours' notice.

The proper treatment of insanity is daily becoming more complicated and individual, and, moreover, it is very expensive. I doubt if, except for the wealthy who can afford to have the aid of special advice and of any known form of treatment, it can be carried on successfully in the small private homes to which Dr. H. Rayner, in his letter to you of Feb. 7th, so properly objects. The question is full of difficulties. If—as seems to be now held—there is a demand for hospitals for the treatment of incipient insanity where no certification and no inspection is required, by all means let the demand be met, because it may turn out that we have been unnecessarily cautious, and that certification and registration are mere bogies to which we have accorded undue reverence, but I doubt if the public will be really satisfied unless there is some guarantee that the Lunacy Commissioners sanction all that is done in them. People generally have no idea of the numberless ways in which certificates and the supervision of the Commissioners protect the patients, and how they ensure that no new treatment nor anything out of the common shall be attempted before the consent of the friends is obtained.

Once certificates and supervision are abolished there is no limit to the machinations of unscrupulous persons, and many people who are now going about freely owe more than they think to the fact of the safeguard of certificates, as but for them many would certainly find themselves in captivity. I know of such cases. I should like to see the French plan of "*conseil de famille*" introduced into this country—an arrangement by which the members of a family meet in conclave, discuss the *pros* and *cons* of the case, and then act in concert. It would prevent much bickering and misunderstanding.

Brain disease when it constitutes insanity is a terrible thing for a family, and all must sympathise with any proposal which shall relieve the patient and friends from the fear of its being known. Therefore it is fitting that if the certificate does stand in the way of early treatment—a statement which is, I think, much exaggerated—the trial of a method by which free and unimpeded treatment may be obtained should be seriously contemplated. In the meantime is it altogether wise to join the chorus of those who keep on reiterating the words "slur and stigma" in connexion with certification? Surely, knowing the security afforded by these safeguards, we should use every endeavour to reassure the public and to make them see that certificates are but the legal expressions of a condition which already exists, and that it is not the certificates which make the insanity, whilst the difficulties and the dangers in the making of them are all in favour of delay in their employment except when other means have failed to cure or safeguard the patient.

We want the public to understand that we are quite ready to make trial of the new experiment, but perhaps under certain conditions, some of us think, such as notification and some degree of supervision, questions upon which the opinions of the Commissioners in Lunacy ought to have the greatest weight. I am, Sir, yours faithfully,

Weymouth-street, W., March 2nd, 1914. T. CLAYE SHAW.

A COMPARISON OF THE ACTIONS OF CHLOROFORM AND ETHER ON BLOOD PRESSURE.

To the Editor of THE LANCET.

SIR,—A paper by Dr. H. P. Fairlie, anæsthetist to the Royal and Western Infirmaries, Glasgow, appeared in THE LANCET of Feb. 28th, the last paragraph of which reads as follows: "Based on those observations I think that ether is the anæsthetic of choice for short operations or for those operations where little shock is anticipated, while chloroform is better for prolonged operations and for those where considerable shock is anticipated."

I am tempted to reply to his paper as it appears to me that he arrives at certain conclusions based on those observations which in the light of present knowledge are most certainly erroneous. He has fallen into the common error that low blood pressure causes shock and is synonymous with it. He accepts Crile's theory of shock, "that it is a condition resulting from a fall in general blood pressure due to exhaustion of the vaso-motor centres." This theory has been proved to be untenable by numerous observers. Seelig and Lyon have shown that stimulation of the central end of the cut vagus causes a rise of blood pressure, and that the rise occurs even when the animals are deeply shocked, showing that the vaso-motor centre is still perfectly active.

Numerous other observers, approaching the subject from different points of view, have shown that the vaso-motor centres, far from being easily exhausted in shock, do their duty practically to the end. In this country Malcolm has written profusely on the subject, and many of his ideas on blood pressure and shock are generally accepted. The Malcolm *versus* Mummery controversy is still green in the minds of those who are interested in the subject.

I quite agree with Dr. Fairlie that a sudden fall of blood pressure during an operation may well mean shock and may be due to the anæsthetic, but I fail to see how he can attribute a fall of blood pressure, in which there is practically no change in the pulse-rate nine hours after the operation, to the ether which he administered during the operation. There may be other explanations (see Chart 4). He gives us no clinical data as to the condition of the patient apart from the blood pressure—one man with a blood pressure of 100 may be *in extremis*, while another may be little affected; this shows the error of considering blood pressure as synonymous with shock. Judging from the Charts 3 and 4 in Dr. Fairlie's paper I would not expect that either of the cases would be classified as operations which had involved a severe degree of shock.

Referring to the post-operative condition he writes as follows: "At a time when it is of vital importance that patients should make use of all their resources, after chloroform anæsthesia they are better able to do so than after ether." If Dr. Fairlie is correct it means that almost every surgical clinic in the world is wrong, and that practical experience has gone for nothing. Chloroform has had its day—open ether has ousted it completely. Chloroform is much the more toxic drug; it is more difficult to administer safely and is much more conducive to shock. All experience goes to support this statement. Chloroform should never be used alone, and never as the terminal anæsthetic. Whenever I see it administered I always think what a foolhardy procedure it is—a highly dangerous drug is being administered in quite unknown doses. I can hardly conceive a condition, at any rate in hospital practice, in which there is any excuse for administering it. In a few clinics chloroform is still used in special cases as an introduction to open ether, but I am doubtful if it is advisable in many of those cases.

Scotland, the home of chloroform, stuck to its own far longer than was justifiable. I am glad to see it banished or nearly so. We have much to learn from the American surgeons on the subject of anæsthesia. They are ahead of us, and the further west you go the further on they are. Just as open ether has displaced chloroform, so it in its turn is being displaced by nitrous oxide and oxygen, a combination which is suitable in a large percentage of cases. Undoubtedly it has disadvantages. It requires special apparatus and special knowledge, but its advocates can say of it that it is the safest general anæsthetic known, being practically nontoxic.

Gas and oxygen when combined with local anæsthetics and sedatives according to Crile's anociassociation method[1] is claimed to have solved the problem of shock. The technique is complicated, requiring time and trouble, but I do not think that there is any doubt that the results justify the proud claims that have been made for this method. It is certainly a great advance, and I would suggest that Dr. Fairlie should compare his charts with those of Bloodgood, published in the Annals of Surgery, December, 1913, in which anoci-association method has been carried out.

In the light of present knowledge it is hardly fair to subject patients whose ability to stand an operation of very great magnitude is highly problematical to a more dangerous anæsthetic than gas and oxygen properly administered; and anæsthetists highly trained in the use of gas and oxygen are much needed for major operations. As to Dr. Fairlie's recommendation to start with ether and continue with chloroform, surely in spite of all theories to the contrary this is exceedingly bad advice. I have had more frights when seeing this method carried out than any other. Your anæsthetist, unfortunately very frequently quite inexperienced, is requested to administer ether by the open method. Owing to his faulty methods he fails to keep the patient under sufficiently, and on being remonstrated with pours in a liberal supply of chloroform; the patient, who is breathing deeply under the influence of the ether, rapidly gulps down a large dose of chloroform, a highly toxic drug, and the result is just what one would expect, the patient's respiration or circulation fails. I fully realise that the above sequence of events is not so likely to occur in the hands of an expert.

I may say I have substituted my chloroform bottle in my midwifery bag for a larger one which contains ether, and I have every reason to be satisfied with the change. All honour to the discoverer of chloroform, but his discovery has had its day, and I hardly think that Dr. Fairlie will resurrect it by his blood pressure observations.

I am, Sir, yours faithfully,
G. MCCALL SMITH, M.B., Ch.B. Edin.,
F.R.C.S.Edin.
Perth, Feb. 28th, 1914.

PAROXYSMAL TACHYCARDIA IN A CHILD.

To the Editor of THE LANCET.

SIR,—In your issue of March 7th is recorded a case of this kind which was shown at the Royal Society of Medicine. Dr. G. A. Sutherland, I see, asked what was the prognosis. Little, I think, is known on this point, and therefore it may interest your readers to know that a patient whom I saw when she was 11 years old, and described in the Clinical Society's Transactions, vol. xxx., in 1897, is now a stewardess on an Atlantic liner. I believe Dr. Sutherland, who was my colleague at the Paddington Green Children's Hospital, saw her with me at the time. I am, Sir, yours faithfully,

W. P. HERRINGHAM.
Wimpole street, W., March 9th, 1914.

GANGRENE OF THE INTESTINE.

To the Editor of THE LANCET.

SIR,—The case of acute suppurative appendicitis complicated by gangrene of the ileum published by Mr. Basil Hughes in THE LANCET of March 7th is of interest from more than one point of view.

In the first place, the condition of anæmic gangrene which obtained is one of great rarity when it involves the intestine. In a recent monograph[1] I was able to collect 9 cases only of anæmic infarction of the intestine; of these cases 6 and possibly 2 more involved the ileum.

With regard to the pathology of anæmic infarction of the intestine one may say that no entirely satisfactory hypothesis has been brought forward to explain all the facts, though it appears that a gradual cutting off (*e.g.*, by endarteritis, arteriosclerosis, or atheroma of the mesenteric branches) of the arterial circulation is an important factor. Embolism alone in practically all cases leads to hæmorrhagic lesions ranging from a few petechiæ on the one hand to infarction on the other.

A second interesting feature of Mr. Hughes's case is the history. There appears to have been a period of relative freedom from symptoms after the acute onset. This "latent" period was followed by further acute manifestations. The course of events therefore was more in accordance with what one might expect in a case of
due to venous thrombosis a
appendix than in one of a
intestine.—I am, Sir, yours faithfully,

LESLIE B. C. TROTTER, M.A., B.C. Cantab.
Ledbury, Herefordshire, March 9th, 1914.

---

[1] THE LANCET, July 5th, 1913, p. 7.

[1] Embolism and Thrombosis of the Mesenteric Vessels.

puffiness in the tissues round the knee, but the joint itself remained perfectly free from any swelling or effusion. The effect of putting the leg up in the straight position was seen when the pain and puffiness subsided in about 10 days and the leg could be flexed; it was then found that movement was as limited as before, the adhesions apparently having united again. Three weeks from the date of the first attempt I had the performance repeated, but this time had the leg left as strongly flexed as was possible, passive movements being started 48 hours afterwards and continued daily. The course was just as free from trouble as before, though the pain was greater on account of the passive movements. However, in three weeks' time I was walking about with a useful limb, and to-day, seven years afterwards, I can flex it to about two-thirds of a right angle—i.e., sufficiently for most purposes.

Though hæmophilia is a rare disease I bring this point forward, as it is one of considerable importance to a hæmophilic. Movement may be so limited in a joint by adhesions that if the surgeon through over-caution fears to break them down, the sufferer is perforce compelled to live a crippled and perhaps an invalid existence. Whereas if it is recognised that movement may safely be restored then the patient may be able, as I was, to follow his profession once more and earn his own living.

I am, Sir, yours faithfully,

March 3rd, 1914. HÆMOPHILIC.

THE NATIONAL INSURANCE ACT.

MEDICAL CARDS RETURNED BY THE DEAD LETTER OFFICE IN MIDDLESEX.

THE Middlesex Insurance Committee finds that out of 206,484 medical cards sent by post to insured persons 12,054 have been returned through the dead letter office, and a still larger figure is given with regard to insured persons not traced by the committee. Naturally the county is one in which a large proportion of the working population is continually on the move either within the county or to places beyond its boundaries. The committee proposes to appoint a registrar at a salary of £200 a year to deal with the matter.

BOROUGH OF LAMBETH INSURANCE PRACTITIONERS' ASSOCIATION.

At a meeting of the executive committee of this association held on Feb. 28th recommendations were drawn up dealing with the allocation of insured sick persons in Lambeth who have not chosen a panel doctor. A report of the working of the association was presented by the honorary secretary. This report will be presented to the general meeting of the association to be held at the Horns Hotel, Kennington, on Tuesday next, March 17th, at 9.30 P.M., when Dr. C. Addison, M.P., has consented to attend and address the meeting on the present position under the Insurance Act. Insurance practitioners from other districts are invited to attend, and admission will be by private card.

THE LONDON INSURANCE COMMITTEE AND INQUESTS.

Coroners in London have been requested by the Home Office to arrange for the London Insurance Committee receiving information as to cases of deaths of insured persons in which they are likely to be interested.

"SURPLUS FUNDS" IN LONDON.

Mr. H. Bazett, of St. Mary's-terrace, Paddington, and Dr. A. R. Eates, of 12, Thayer-street, Manchester-square, are organising a meeting to be held at the house of the latter on Tuesday next, March 17th, at 3 P.M., in response to a large number of letters they have received from panel doctors who are interested in the manner of dealing with these funds proposed by the London Insurance Committee. The object of the meeting is to take concerted action to test the legality of the proposed action of the committee. All panel doctors with small lists are cordially invited to attend.

NATIONAL MEDICAL UNION.

At a meeting of the London Organisation Committee of the National Medical Union held at 346, Strand, on March 9th, the following resolutions were passed unanimously:—

1. That the London Organisation Committee of the National Medical Union repudiates the action of the Metropolitan Counties Branch of the British Medical Association in attempting to elect a Local Medical Committee for London which would be unrepresentative of the profession and prejudicial to the interests of non-panel practitioners.

2. The London Organisation Committee of the National Medical Union recommends practitioners not on the panel to refrain from nominating candidates, allowing themselves to be nominated, or otherwise taking part in this election.

The secretaries were instructed to forward copies of these resolutions to the press, and also to circularise all medical practitioners resident in the county of London and not on the panel on the subject.

The circular is signed by Mr. E. Arthur Dorrell and Dr. Robert Carswell as honorary secretaries of the National Medical Union.

MANCHESTER INSURANCE COMMITTEE.

Mr. L. Lloyd Jones, chairman of the finance sub-committee, brought forward at a recent meeting of the Manchester Insurance Committee his resolution announced some time ago, "that the medical sub-committee be requested to investigate and report not later than September next as to the desirability or otherwise of establishing a full-time medical service for insured persons and their dependents at the commencement of the year 1915." The mover relied upon the allegation that insured persons were not getting the attention to which they were entitled from very many of the medical men on the panel. He contended that the system adopted encouraged the undertaking of too many patients and an excessive number of visits and consultations and did not encourage the prevention of disease. The societies had to pay sickness benefits upon certificates too easily obtained. He referred to the figures published with reference to the past year as showing £162,284 claimed by medical men as against £150,040 allowed, claims for £12,244, which he estimated as representing over 110,000 visits, being disallowed. He referred to the unequal amounts payable to the various members of the panel and to the large sums earned by several of them, also to the position of the druggists as affected by a disallowance of 110,000 consultations. He advocated a full-time medical service with an income limited to £800 a year. Discussion took place in which Dr. McGowan pointed out that the circumstance of congested districts existing was responsible rather than any fault of the medical practitioners for the conditions complained of; and an amendment was moved by Mr. H. W. Irwin that "the Medical Subcommittee be requested to investigate and report not later than September next on the present system of medical service, and if such system is found unsatisfactory to recommend some alternative system." This was carried unanimously, Mr. Jones withdrawing his resolution. Another resolution was passed at the same meeting instructing the Sanatorium Subcommittee to furnish detailed returns showing (1) number of insured persons applying, medically examined, and recommended for sanatorium benefit; (2) number of cases of tuberculosis receiving treatment; and (3) results in cases receiving treatment.

Sickness in Industrial and Agricultural Districts.

The sickness returns of the Manchester Unity of Oddfellows show the difference between the conditions of industrial and agricultural districts, provision for which is made at a uniform rate by the Insurance Act. The actuarial estimate of sickness benefit is given as 9*s.* 9*d.* for men and 6*s.* 6*d.* for women, the former having proved sufficient and the latter too low. The actual cost in the case of men is found to be in Lancashire 8*s.* 11*d.*, Cheshire 8*s.* 4*d.*, and Kent 6*s.* 11*d.*, and in the case of women in Lancashire 8*s.* 8*d.*, Cheshire 7*s.* 4*d.*, and Kent 5*s.* 5*d.*

Medical Incomes under the National Insurance Act.

The incomes from insured patients earned by medical men practising at Bradford may be compared with the figures given in THE LANCET of Feb. 28th, p. 649, for Manchester and Leeds. At Bradford during the past year seven medical men earned between £1000 and £1500, two between £800 and £1000, both of these making less than £900, 15 between £500 and £800, 32 between £300 and £500, and 13 between £250 and £300, and 29 made less than £50. From this it will be seen that 45 making between £250 and £500 a year represented a considerable portion of those on the panel, the total of which was 117. The largest income was made by a practitioner with 4000 patients on his list and no partners, with which may be compared the list of 5177 credited to one medical man on the panel in London. In the metropolitan district out of an average total of 909 medical men upon the panel, 172 have lists of more than 2000, the number which the Insurance Committee desires to establish as a limit, 340 have been 1000 and 2000, and 500 have less than 500.

The West Riding Insurance Committee.

At a recent meeting of the West Riding Insurance Committee it was stated that the number of patients admitted to sanatoriums was 641. A considerable amount of work was being done in the treatment of consumption, but difficulty was being experienced in the finding of suitable ground for the erection of sanatoriums. A prolonged discussion took place upon the question whether a list of the medical men upon the panel with the number of their patients should be supplied to each member of the Insurance Committee or only to members of the Medical Benefit Subcommittee, as recommended by the latter body. The amendment which proposed that the information should be given to the whole committee was strongly opposed by medical members, but was eventually carried by a large majority.

The Limiting of Panel Practice.

With regard to the limiting of the number of patients to be undertaken by any member of a panel, the proposal of the Medical Benefit Subcommittee at West Bromwich may be mentioned, as differing in form, if not in principle, from others which have been observed. The subcommittee recommended that in accordance with the Insurance Commissioners' opinion no arbitrary limit should be fixed, but that there should be a resolution of the Insurance Committee that it was undesirable that one practitioner should undertake more than 2500 persons, and also that in the present and in future years allocations for the purpose of distributing surplus funds should not cause the number of persons on any medical man's list to exceed 2500.

Bournemouth Insurance Committee.

In the report of the Sanatorium Subcommittee presented to the Insurance Committee at Bournemouth the following figures relating to the period from Jan. 15th, 1913, to Jan. 11th, 1914, were given. Number of persons who had applied for and received sanatorium treatment 75, 38 being men and 37 women; cost of institutional treatment for 25 men and 27 women, £825; cost of domiciliary treatment for 40 men and 31 women, £725. The Medical Benefit Subcommittee reported that medical treatment had been supplied to 126 temporary residents. The same body recommended that the report of the committee considering the question of malingering be waited for before steps should be taken in the matter of apppointing a medical referee. Upon this a discussion took place with regard to medical referees and the question of malingering, the appointment of a referee at Bristol and its results being referred to. A speaker, Mr. Bartlett, spoke of the stories of malingering as exaggerated, and said that in the society which he represented payments in respect of sickness benefit during the past 18 months had, if anything, been less than in previous periods. The chairman suggested that returns from various societies would be desirable before any conclusion was arrived at, and further consideration of the question was postponed.

West-end Hospital for Nervous Diseases.—The annual meeting of governors of this institution was held on March 3rd, the chair being taken by Mr. Leonard Brassey, M.P. It was reported that the income for 1913 amounted to £7430, as compared with £6798 in 1912 The total expenditure was £7907, as compared with £6350 in 1912; but repayment of debt and such items accounted for £1792 of this, compared with £408 in 1912. An average of six additional cots had been maintained in 1913. The debt had been reduced from £5431 to £3660. Patients treated in the wards numbered 273, and the average duration of their stay in hospital was 62 days. New out-patients numbered 2521, and the total of out-patients' attendances was 29,046. The total of massage and electrical treatments given was 22,091, against 19,030 in the previous year. By the exercise of much care the weekly cost of an in-patient had been reduced to £1 11*s.* 7*d.*, and the cost per out-patient visit to 10·35*d.* The urgent need of the extension and rearrangement of the hospital was universally recognised, but a large sum was required before building operations could be commenced. Appeal was made for aid to extinguish debt, for rebuilding the hospital, and for maintaining the annual subscriptions.

Medical News.

University of Cambridge.—The following medical degrees have been conferred :—

M.D.—P. H. Bahr, Trinity; and R. M. Courtauld, Pembroke.
M.B., B.C—H. W. Willcocks, Caius; E. J. Bradley, Jesus; and A. C. Clifford, Emmanuel.
M.B.—J. M. Jarvie, Emmanuel.

The Senate of the University are voting to-day (Saturday), at 2 P.M., whether application shall or shall not be made for a Government grant for the assistance of the medical department of the University. A *non-placet* notice has been circulated, with some important signatures, which sets out the alleged risks of putting the teaching of the University under Government control. All medical members of the Senate are therefore earnestly requested to support the Grace by their votes, and fly-sheets have been issued to the Senate of an unusually forcible kind. All the professors and lecturers in medical subjects append their names to a refutation of the *non-placet* circular; a second fly-sheet is signed by the professors, readers, and lecturers in allied subjects; while a third fly-sheet, supporting the views of the Medical Board, is bound to have great influence with the constituency, as it is signed by 47 of the best known among the teachers of the University "unconnected with those departments which are concerned with the teaching of medical students."

Royal Medical Benevolent Fund.—At the February meeting of the committee 26 cases were considered and grants amounting to £278 voted to 23 of the applicants. Appended is an abstract of the cases relieved :—

Widow, aged 58, of M.R.C.S., L.S.A. Since husband's death about a year ago has supported herself as nurse companion but has recently been obliged to give up the post and requires assistance whilst obtaining another; children unable to help. Voted £5.—Widow, aged 45, of M.R.C.S., L.R.C.P. Receives a small sum quarterly as payment for the practice but requires a little help for unavoidable expenses; two children, aged 16 and 14. Voted £5.—M.D. St. Andrews, aged 76. Has done excellent work as visiting physician to different institutions but has never had much private practice and has now come to an end [illegible] the infirmities of old age. [illegible] 61, of M.R.C.S., L.R.C.P. [illegible] r children and is now quite unprovided for. Voted £12.—Daughter, aged 32, of L.R.C.P., L.R.C.S. Used to be a mental nurse, but for several months past has been in very bad health, and is ordered a change which she cannot afford. Voted £10.—Widow, aged 59, of L.R.C.P., L.R.C.S. Irel. Supported her husband during a long illness, and is now quite broken down in health; children unable to help. Voted £18.—Widow, aged 58, of L.R.C.S. Edin. No income; precarious earnings from needlework and letting lodgings and slight help from children. Relieved five times, £6. Voted £12.—Daughter, aged 66, of late M.R.C.S., L.S.A. Was comfortably provided for by her father, but was defrauded by her trustee, and is now dependent on a small annuity from a charitable society. Relieved three times, £48. Voted £12.—Widow, aged 83, of M.R.C.S., L.S.A. Has a small income, but is obliged to ask for assistance owing to the afflictions of her children, three of whom are deaf and dumb. Relieved 11 times, £70. Voted £10.—Widow, aged 65, of M.R.C.S. After husband's death endeavoured to establish a boarding house at the seaside, but lost all her capital. Now has a situation as cook, but feels she is unequal to the work, which is very hard. Relieved three times, £36. Voted £12.—Widow, aged 47, of L S.A. Two children, aged 11 and 9, and finds her small income insufficient for unavoidable expenses. Relieved once, £5. Voted £12.—Daughter, aged 58, of late M.R.C.S. Is mentally afflicted and obliged to live under supervision at the expense of two sisters, who each have to earn their living. Relieved nine times, £81. Voted £10.—M.D. Edin., aged 53. Met with a severe accident two years ago, and is not able to support himself again; dependent on a widowed sister whose income is small. Relieved once, £12. Voted £18.—Widow, aged 67, of L R.C.P., L.R.C.S. Edin. Supplements a pension from a charitable society by teaching and letting lodgings, but has had her rooms empty for several months and has incurred unavoidable expenses through the illness of her daughter, who is a governess. Relieved 14 times, £102. Voted £10.—Daughter, aged 47, of late F.R.C.S. No income, and incapacitated by gastric ulcer. Relieved 15 times, £129. Voted £12.—Daughter, aged 53, of late F.R.C S. No income and such indifferent health that she finds it most difficult to get a situation and impossible to retain one. Relieved eight times, £52. Voted £12—Widow, aged 45, of M.B., C.M. Edin. Left unprovided for at husband's death after a long illness; seven children, of whom three are self-supporting and the remainder dependent. Only income £12 a year from another society. Relieved twice, £32. Voted £20.—Daughter, aged 57, of late M.R.C.S. Health so indifferent that she can only earn a few shillings a week and is practically dependent on this Fund and [illegible] six times, £95. Voted £18.—Widow, aged [illegible] her right hand several years ago, and has fou[illegible] to obtain employment; slight help from chi[illegible] £118. Voted £12.—Widow aged 46, of L.S.[illegible] for at husband's death three years ago and endeavours to support herself by letting lodgings at a seaside resort, but has had a very bad season. Two children, aged 10 and 8. Relieved once, £5. Voted £10.—Daughter, aged 62, of late M.R.C.S. Only income a small Government annuity purchased a few months ago with a legacy, and suffers from a permanent affliction which renders occupation practically impossible. Relieved three times, £36. Voted £6.—Widow, aged 40, of M.B., C.M. Aberd. Only income a small monthly grant from another society, and is incapacitated by a chronic complaint. Two children, aged 14 and 13. Voted £12.—Daughter, aged 42, of late M.D. St. And. Has supported herself for some years by massage, but broke her right forearm some months ago and is still incapacitated. Relieved twice, £20. Voted £10.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

University of Oxford.—The following appointments have been made: Dr. Walter Ramsden, University Lecturer in Chemical Physiology; Mr. A. P. Dodds-Parker, University Lecturer in Applied Anatomy: and Dr. S. E. Whitnall, University Demonstrator of Human Anatomy.

Exeter Dispensary.—The annual meeting of the subscribers of the Exeter Dispensary was held on Feb. 26th. The medical report stated that the number of recommendations made was 3732, against 4654 in 1912, the decrease being due to the National Insurance Act. The financial statement showed a diminution in subscriptions, and a deficit of £390 remained at the close of the year.

Devon and Exeter Dental Hospital.—The thirty-fourth annual meeting of the subscribers to this institution was held on Feb. 27th. The report showed that 3231 cases had been treated during 1913, making a total of 144,931 since the foundation of the hospital. The financial statement was satisfactory. The committee states that through the kindness of Mrs. Nosworthy, who contributed £500 for the scheme, a fund has been inaugurated for granting assistance to deserving patients requiring artificial teeth.

Radium for Use at Manchester.—At a meeting on March 9th of the general committee dealing with the administration of the radium which it is proposed to purchase for the Manchester hospitals it was decided that the Manchester Royal Infirmary is to be the place where the radium should be stored. It was also agreed that the board of management of the Royal Infirmary should consider the propositions put forward by the scientific members of the general committee with regard to the administration of radio-emanations and report to a further meeting of the committee.

Royal Portsmouth Hospital.—The sixty-fifth annual meeting of supporters of this hospital was held in the Town-hall on Feb. 27th. The report stated that there had been an increase of 8 per cent. in the in-patients, a decrease of 13 per cent. in the out-patients, and a falling off in the casualties of 12 per cent. This experience agreed with that of other voluntary hospitals. The ordinary expenditure had been a record, £9606; and the ordinary income had also been a record, having amounted to £7528, leaving a deficit of £2078. Legacies had been received to the amount of £1200, reducing the deficiency to £877. The hospital had been approved under the National Insurance Act for the reception of suitable cases of tuberculosis, for which the Local Insurance Committee were empowered to pay. Satisfaction was expressed at the formation of a pathological department, which would enable the hospital to keep abreast with advances in medical science, and extend its work in the direction of research.

Imperial Health Conference.—Several questions of interest to the medical profession will be considered at the Victoria League Imperial Health Conference and Exhibition to be held at the Imperial Institute in May next. A special section will be devoted to the Care of Child Life, and amongst those who have promised papers are Dr. Charles A. Hodgetts, medical adviser to the Commission of Conservation in Canada; Dr John McCullough, chief medical officer of health, Toronto; Dr. Isabel Ormiston, medical officer to the Education Department of Tasmania; and Dr. Truby King, New Zealand, on the Hygiene of Childhood. In connexion with the conference an exhibition dealing with the Care of Child Life, and also showing the influence that town planning may have upon the health of the future citizen, is being organised. In this there will be a collection of models, charts, diagrams, and statistics.

Mr. T. Nicolson, of the Co-partnerhip Tenants Housing Council, 6, Bloomsbury-square, London, W.C., is organising the exhibition.

A CENTENARIAN.—Mrs. Charlotte Webb, of Bilson, Cinderford, died on Feb. 22nd. She celebrated the 103rd anniversary of her birthday on Feb. 17th.

THE annual dinner of the British Oto-Laryngological Society will take place on the evening of Wednesday next, March 18th, at the Trocadéro Restaurant, Piccadilly-circus, W., at 7.30 o'clock. Mr. Charles J. Heath will be in the chair.

ST. GEORGE'S HOSPITAL: THE HUNTERIAN SOCIETY.—The annual dinner of the St. George's Hospital Hunterian Society will be held to-day, Friday, March 13th, at the Waldorf Hotel at 7 for 7.30 P.M. The chair will be taken by Mr. W. Fedde Fedden, F.R.C.S., and Mr. A. William West will be the guest of the St. George's Hospital Club on the occasion of his retirement from the post of treasurer to the hospital. The dinner will be followed by a smoking concert, presided over by Dr. Charles Slater, president of the club. It is hoped that many of St. George's men who have not already intimated their intention of being present will at once communicate with the honorary secretaries of the Hunterian Society, St. George's Hospital.

QUEEN VICTORIA JUBILEE CONVALESCENT HOME, DURDHAM DOWNS.—The annual meeting of the friends of Bristol's Convalescent Home was held on Feb. 26th, under the presidency of the Lord Mayor. The medical report stated that during 1913 the patients admitted numbered 1983; 922 of these were female and 1061 male. From the Royal Infirmary came 660 patients, from the General Hospital 655, the Eye Hospital 24, the Dispensary 59, and the Clifton Dispensary 16. Free patients were 398 and paying patients 171. The daily average number of cases was 78¾, the average stay being 14¾ days. The financial statement showed the income was £2943 and the expenditure £2925.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Administration of the Insurance Act.

THE topic of the debate which arose on the Vote on Account on Thursday, March 5th, was the administration of the National Insurance Act. For the most part the discussion related to the controversial subject of the solvency or insolvency of Approved Societies. There were, however, references to medical matters in the debate, and to these the following report is entirely confined.

Mr. WORTHINGTON EVANS, in moving as an amendment the reduction of the Vote by £100, criticised the action of the [illegible]

[illegible] believed that that was something like 25 per cent. of the whole. Of course, if 25 per cent. of all insured people in the country had not selected a doctor it would be a very large figure, but the conditions of London were peculiar, and consequently the percentage in London was likely to be very much higher than the percentage throughout the country. He did not believe, however, that it was any exaggeration to say, taking the figures throughout the country, that there was something between 5 and 10 per cent. at least of insured people who had not selected a doctor. That meant that there were something like 1,000,000 people who had not selected a doctor, although they were charged by a deduction from their wages for the payment of a doctor. [illegible] they were getting no [illegible]

sum. Counsel's opinion [illegible]

[illegible] in the Regulations to [illegible]
mittee retained it in [illegible]
was interviewed by a [illegible]
who asked if those [illegible]
Insurance Committees would be paid over to the panel doctors. He was reported to have said, "Yes, even if counsel's opinion should once more prove unfavourable, the doctors are to get the money." The deputation, it was said, had gone away pleased. He submitted that it was of public utility to know which of the insured were being charged without getting benefit. It was of public utility to know how £300,000 or £400,000 which was contributed by these insured people was to be used. The doctors might be entitled to it. He did not know whether they were or not. If they were [illegible]

[illegible] of large numbers of insured persons stood in the way of compiling a return showing ho[illegible]
a medical man on the panel. [illegible]
in saying that in the county [illegible]
[illegible]0 insured persons [illegible]
The whole of the [illegible]
were collectively [illegible]
[illegible]sured population of Middlesex, and his committee had deliberately avoided assigning healthy insured persons to a doctor, because they had the assurance, which he was bound to say had been [illegible] were responsible and [illegible]
the insured population [illegible]
[illegible]der a score of cases where persons had been ill and had neglected—it was their own fault—to select a doctor. That had led to an hour or two of difficulty, but a doctor had been communicated with and these people had been assigned with the doctor's consent to a doctor in the vicinity. If it was a fact that every insured person in the county who had been ill had had a doctor, what nonsense it was to say that because certain people were not on a doctor's list they had not had the medical benefit for which they paid. It might as well be said that people on a doctor's list who had been fortunate [illegible] had medical benefit. [illegible]
[illegible]ed in Middlesex was [illegible]
[illegible]ry, and indeed under [illegible]
normal course with [illegible]

never was any balance [illegible]
there [illegible]
had made a contract wi[illegible]
capita- [illegible]
of the [illegible]
s breach of [illegible]
the money [illegible]

Mr. GODFREY LOCKER-LAMPSON dealt at length with the payments to panel chemists for the most part in the Manchester district. So far as he could see there would be an average loss of about £100 a head to the Man- [illegible]

was also a very serious shortage in the funds under the Insurance Act available to [illegible]
tuberculous insured persons [illegible]
In the last minutes of the Gla[illegible]
was stated that 27 persons were awaiting admission to [illegible]
[illegible] persons receiving domiciliary [illegible]
[illegible] a scandal [illegible]

[illegible] course of his speech, said that [illegible]
was 2*s*. per person. In the old [illegible]
[illegible]r member covered drugs and [illegible]
a system by which the doctors got 7*s*. and 2*s*. were given for drugs. That fact had to be kept in mind. The Government had never undertaken to give a [illegible]

that margin. In certa[illegible]
prescribing very freely. [illegible]
the first few months. [illegible]

comment on how that occurred. It had been especially the case where the doctors had chosen the method of payment by attendance. That also was rather significant. Matters were being scrutinised by the Pharmaceutical Society. He did not know that they were bound to pay bills of this kind in excess of the very liberal and generous allowance made. They desired to know the reason why these extravagant bills had been sent in—extravagant he meant on the face of them—for he did not want to make a general charge. They had got to examine these accounts very carefully. They had to see whether the doctors prescribed fairly and reasonably or whether they prescribed in order, in some cases, to get rid of their patients—whether they prescribed drugs and sent to the chemists unnecessarily. It would be folly on the part of the Government not to examine these things. Meanwhile, all the chemists concerned had again gone on the panel, which showed that they, at any rate, were perfectly satisfied to go on on the old terms whilst these cases were being examined. He now came to the question of sanatoriums. Nobody ever thought that in the course of 18 months after the Act came into operation a perfect system of sanatoriums and dispensaries would be ready. As to sanatoriums it was very difficult to move the municipalities. The Government only promised money to localities which were prepared to meet them. The Government had provided £1,600,000. If that had not been all spent it was very largely because time had been needed to bring proposals before the corporations and because there were some slack municipalities as well as some active ones. Just look at what had happened in the meantime. Let them consider the number of people who had been dealt with. There were between 30,000 and 40,000 people who were receiving consumptive treatment of one kind or another. What did that mean? Some of it was domiciliary treatment, which meant that the patients had doctors, and many of those people did not have doctors before at all. They had received very excellent food as well as medicine of a strengthening character to fortify their system to fight the tuberculosis. What about institutional treatment? He agreed that in two, three, or four years there would be more room and more beds, whilst the institutions would improve, but everything could not be done in 18 months. As it was, there were 24,000 persons treated in institutions. Some of these were not good, because they had to be improvised for the time being. But even the least good were infinitely better than the homes in which many of these people had to be treated, or rather to be neglected, in the past. Dealing with the subject of excessive sickness the right honourable gentleman said that it was acknowledged that there was more malingering amongst women's than amongst men's societies. On the other hand, excessive sickness had to be taken into account. If any system of insurance was going to be a success the affairs must be managed in a business-like way. There was a margin no doubt for improvement in the doctoring—a considerable margin, and that was a question which would have to be considered. There were some doctors who were too slack and gave certificates much too readily. Later in his speech the right honourable gentleman said that millions of people were brought into insurance who could never afford a doctor before. Here for the first time these people were on the doctor's list. They could go to the doctor at any time, ask his advice, have drugs prescribed, and it was quite a novel experience for these poor people and for the doctor to deal with them. It was too much to ask the doctors that they should be tested by the first year's experience of conditions to which they had never been accustomed.

Mr. H. FORSTER remarked that honourable Members had some reason to be surprised that only a sum of £88,000 out of £1,500,000 should have been provided for the erection of sanatoriums. More expedition might have been shown by the Government. Domiciliary treatment had fallen lamentably short of what ought to have been provided.

The amendment was afterwards negatived by 242 votes to 174, and the vote was agreed to.

Vaccination Acts.

A Bill to repeal the Vaccination Acts has been presented by Mr. BLACK in the House of Commons. It has been read a first time.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 4TH.

Lunatics as Private Patients.

Sir JOHN JARDINE asked the Home Secretary to state what precautions existed to protect the liberty of the subject where a lunatic who had not been personally seen by the judicial authority had been received as a private patient by the manager of an institution for lunatics or by a person taking charge of him as a single patient; what means the Lunacy Commissioners had at their disposal for enforcing the requirement of the Lunacy Act, 1890, Section 8, Subsection (2), that such manager or person should within 24 hours after reception give the patient a notice in writing of his right to be taken before or visited by a judicial authority; whether such manager or person was bound forthwith t inform the Lunacy Commissioners or the judicial authorit that he had discharged this duty of giving notice to th patient or to make any other record of his having given th notice and of the answer of the patient; and in [illegible] to comply with the law requiring [illegible] whether the Lunacy Commissioners exercised any powers o discipline or on discovery originated any prosecutions for th misdemeanour.—Mr. MCKENNA replied: When a patient ha not been seen by the judicial authority who made th reception order, in addition to the precautions applicabl to all private patients, he has the right to be seen by another judicial authority, and to receive notice of such right within 24 hours of admission, unless the medical officer or th medical attendant signs and sends to the Commissioners a certificate that the right would be prejudicial to the patient. The only means the Commissioners have of enforcing the duty of giving this notice is a prosecution for misdemeanour in case of default. There is no obligation to inform either the Commissioners or the judicial authority that the notice has been given to the patient, but if the patient desires to be seen by a judicial authority a notice to this effect must be sent to the judicial authority of such desire. The Commissioners on becoming aware that the required notice had not been sent would call the attention of the person in default to the requirements of Section 8 and warn him of the risk he incurred of a prosecution. A prosecution would not be instituted for mere inadvertence, but only for wilful disobedience to the law.

Visitation of Broadmoor Criminal Lunatic Prison.

Mr. TOUCHE asked the Home Secretary what was the object of the visit of the Lunacy Commissioners to the Broadmoor Criminal Lunatic Prison; and whether they went to grant interviews and consider representations made by prisoners in favour of release.—Mr. MCKENNA answered: The Commissioners in Lunacy visit Broadmoor in pursuance of Section 14 of the Criminal Lunatic Asylums Act, 1860, to inquire into the mental and bodily condition of patients confined there, and make such other inquiries as they may think proper. They give the patients full opportunities of laying before them any matter to which they wish to draw attention and receive and inquire into any complaints made by the inmates.

The Letters of Inmates at Broadmoor.

Mr. TOUCHE asked the Home Secretary whether any record was kept of the letters written to the prison authorities by prisoners in the Broadmoor criminal lunatic prison; and if these letters were read by the governor.—Mr. MCKENNA answered: Broadmoor is not a prison and is not under the prison authorities. A record is kept of every letter received or dispatched by a patient. All those dispatched are read by some member of the medical staff, but not necessarily by the superintendent. There were nearly 24,000 last year.

Death of an Insured Person.

Mr. CASSEL asked the Secretary to the Treasury whether his attention had been called to the opinion expressed by a coroner's jury at the inquest on George John Chandler, deceased, an insured person suffering from tuberculosis, that there had been neglect on the part of the insurance officials, and that more care should be taken on all future occasions; and whether the Government proposed to take any steps in the matter.—Mr. WEDGWOOD BENN answered: My right honourable friend's attention had already been called to the inquest referred to, and he has caused the fullest possible inquiries to be made. The deceased applied for sanatorium benefit on Jan. 12th, 1914. He was examined on Jan. 13th, and on the same day he and the doctor in attendance were officially informed that domiciliary treatment had been granted, the latter being invited to forward any requisition for an allowance of special nourishment which in his opinion would be beneficial to the patient. The domiciliary form of treatment was recommended on the advice of the Insurance Committee's medical adviser, who reported that the patient's condition would not admit of his being removed to a sanatorium. Had the case been suitable for treatment in a sanatorium the patient would have been removed to one within three days, as the Committee had at the time seven beds available. No trace whatever can be found in the Insurance Committee's offices of any application for an allowance of special nourishment, and the facts elicited by my right honourable friend's inquiries suggest that it is more than doubtful whether any such application was in fact made. The relatives of the deceased state that he received all the nourishment that was necessary, and that every possible attention was shown by the doctor in charge of the case, who had prescribed all suitable tonics and medicines, and had in the interval between the recommendation on Jan. 13th, and the death of the deceased on Feb. 25th, paid over 25 visits to him.

Elementary Education (Defective and Epileptic Children) Bill.

Mr. J. A. PEASE, in moving the second reading of the Elementary Education (Defective and Epileptic Children) [illegible] men. It mig [illegible] stage. The [illegible] Bill compuls [illegible] did propose w [illegible] Act compulsory in regard to suitable special schools for the defectives. There were now about 12,000 children in [illegible] unprovided for who might become wastrels and useless citizens, whereas the greater number in the event of their being sent to special schools would undoubtedly become useful citizens. At least, the [illegible] and to a very large extent [illegible] really a corollary to the Me [illegible] passed last session, and would come into operation on April 1st. It was with a view to enable the work of the Mental Deficiency Act to be properly carried out that the Bill was essential. The cost to the Treasury of the special schools was about £45,000, and ultimately it would be [illegible] riticised by Sir F. [illegible] hers, but the second [illegible]

THURSDAY, MARCH 5TH.

Exemptions from Vaccination in Scotland.

Captain GILMOUR asked the Secretary for Scotland to state the number of exemptions from vaccination in each of the three years before a statutory [illegible] appearance before a magistr [illegible] number of exemptions in [illegible] MCKINNON WOOD wrote in re [illegible] declarations of conscientious [illegible] provision existed, as in England, for the granting by magistrates of exemptions from vaccination. The numbers of such statutory declarations made in respect of births registered in subsequent years were as follows:—

In respect of births registered in—	Statutory declarations.
1907	7,258
1908	15,846
1909	22,746
1910	26,954
1911*	29,582
1912*	32,863

* These figures have not yet been published and are subject to revision.

Housing Conditions in Dublin.

Sir ARTHUR GRIFFITH-BOSCAWEN asked the Chief Secretary to the Lord Lieutenant of Ireland whether the attention of [illegible] led to the recently issued [illegible] mittee on the Housing [illegible] in Dublin, which report [illegible] is state of affairs in that [illegible] een called to the fact that no less than 229 persons per 10,000 lived in one-room tenements in Dublin, whereas the corresponding figures for Liverpool were 23 and for Belfast 3 per 10,000; that several [illegible] houses described as [illegible] t the committee [illegible] erations in Irish [illegible] proposed to take [illegible] committee.—Mr. [illegible] two paragraphs [illegible] cept the figure [illegible] members of the Dublin corporation who own houses which are described by the chief superintendent of the sanitary staff of the corporation as being unfit for human habitation. The question of municipal housing is receiving the consideration of the Government.

Sir ARTHUR GRIFFITH-BOSCAWEN: When will the right honourable gentleman be able to make a statement as to what steps the Government propose to take? Also can he [illegible] in Dublin are so much [illegible] Dublin and other municipal bodies?

[illegible] large question.. Some such [illegible] is worth anything, be given [illegible] before they can be expected [illegible] arden of this very necessary [illegible] Member for Dudley (Sir [illegible] no one in appreciation [illegible], obviously I am not in a position to say when the Government will be able to make really definite and business-like proposals in this matter. They cannot be delayed indefinitely.

Sanatorium Benefit in Dublin.

Mr. GODFREY [illegible] asked the honourable Member for St. [illegible] ct that it was unable to [illegible] the supplying of sanatoria [illegible] there was at present a [illegible] what the Government [illegible] lution referred to, but he is informed that it is not the case that persons awaiting admission to residential institutions are without treatment in the interim.

Payment of Canterbury Panel Chemists.

[illegible] asked the honourable [illegible] negative.

MONDAY, MARCH 9TH.

Medical Cards for Insured Persons in Blackburn.

Mr. ASTOR asked the Secretary to the Treasury whether the collectors of the panel doctors were employed by the Blackburn Insurance Committee to deliver medical tickets to insured persons; how many collectors were so employed; what remuneration was paid to them for this service; how many doctors' collectors had refused to undertake this work; and what arrangements were made to deliver the cards in these cases.—Mr. WEDGWOOD BENN replied: My right honourable friend is informed that in a large number of cases the collectors of the panel doctors were employed by the Blackburn Insurance Committee to deliver medical cards to insured persons, but he is unable to state how many were so employed or how many declined to undertake the work. The remuneration offered was 2*s.* 6*d.* per 100 cards. In those cases in which it was not possible to secure the delivery of the cards by the doctors' collectors the cards were sent by post or delivered by other persons engaged for the purpose.

Insured Persons Refused by Panel Practitioners.

Mr. RUPERT GWYNNE asked the Secretary to the Treasury what arrangements had been made by which an insured person who had been refused medical attendance by three panel doctors could obtain medical benefit without further delay.—Mr. WEDGWOOD BENN replied: Insurance Com- [illegible] power under their agreements with [illegible] n applying to [illegible] lty in getting [illegible] accepted and this power has always been exercised when [illegible]

Free Examination of Sputum.

Mr. ASTOR asked the President of the Local Government [illegible] for the free [illegible]

TUESDAY, MARCH 10TH.

Edinburgh Milk-supply.

Mr. MCKINNON WOOD informed Mr. JAMES HOGGE that it was stated to him that the medical officer of health for Edinburgh stated that investigations carried on for several years showed that only in exceptional cases was the presence of tubercle detected in samples of milk taken in the city. [illegible] cient measures of inspec- [illegible] peration, and that as [illegible] would compare favour- [illegible] cupied a good position [illegible] om all forms of tuberculosis were compared with the statistics for other large towns in Scotland.

AN UNJUST REBUKE.

To the Editor of THE LANCET.

SIR,—Having recently recalled to a friend, also a layman, some experiences over 20 years ago in London, I related the story of an incident which happened to me in a restaurant in Holborn at that time, and my friend seemed very surprised; it occurs to me that others may be interested, and, indeed, I have often wondered if other short-sighted people have similarly suffered I happened to go [illegible] evening for a meal and sat at [illegible] of an hour eating dinner and [illegible] thinking out a little problem, [illegible] probably became, unknown to me, fixed in more or less of a stare. That evening I did not happen to wear my spectacles, and could not distinguish details of anything a few feet away. Just before I rose to go out of the restaurant a man crossed the floor and boxed my ears, much to my astonishment, and said: "Take that, you impudent young bounder, for glaring at me like that." I was too astounded [illegible] thinking the man had taken [illegible] I could jump up to expostu[illegible] te diner never knew the truth that I had never seen him at all. I [illegible] in [illegible]

London, March 9th, 1914. [illegible]

THE EMBERS OF CREDULITY.

THE man who sets out to gather up the vestiges of still lingering superstitious beliefs and quaint customs can have no better field for his operations than that of the more isolated farmsteads and out-of-the-way settlements of the countryside. This fact seems to have been fully recognised by Mr. E. A Rawlence, of Salisbury, who for five years past has, in prosecuting such work, taken advantage of the peculiar opportunities which his professional duties afford of throwing him into close touch with farmers and agriculturists generally. An interesting paper on "Curative Superstitions Still Obtaining in Dorset," which he read before the Dorset Field Club recently, and which was copiously reported in the *Dorset County Chronicle* of Feb. 5th, shows that he has applied himself with much acumen to the quest, and with signal success, as may be judged from the few extracts which we make. It should be stated that the author of the paper very properly [illegible] professions fo[illegible] about. An ol[illegible] zuffered tar'bl[illegible] us boys to Yeovil to have a wonderful receipt made up. We brought it back and put the bottle on the [illegible] med for a long time, and so [illegible] r never had a twing of the [illegible] broke it, and zure enough [illegible] om agin" A leading Dorset [illegible] an toothache was on his wa[illegible] the old client—a farmer. "[illegible] re dentist to have a tooth c[illegible] I'll tell 'e how to cure it Now you goo to a young w'oak tree and put ver y'arms round it, an' mark the place wher' yer vingers mate Then het a zlit in the bark we' yer knife, then put yer left han' behin' yer head and pull out zum hair behin' yer right ear and put it in the zlit o' the bark. Yer'll niver [illegible] The follow-ing cure, possibly of [illegible] Dorset: "Get an honest lav[illegible] ish it in an honest miller's millpond, dry it and iron it with an honest tailor's goose; if you can do that you will never have the toothache again" Mr. Rawlence was assured by a farmer that a "wise woman" whom he had consulted "always picked her herbs at midnight on a full moon, as they were more potent then." "Cures" and charms for warts are numerous, and some are given in the above paper The inquiries to which we have alluded are [illegible] garnered within the pages of a published book, should form an estimable contribution to the folklore of Dorsetshire.

"CHARLEYHORSE."

THIS word sounds veterinary rather than medical, but it is the adopted [illegible] condition at[illegible] analogous t[illegible] knee. Wit[illegible] name for [illegible] accompany [illegible] received a [illegible] teams of [illegible] common in England, as we do not think it will despite its influence in drawing money, there is no doubt many Englishmen will be familiar with the stiffness of the legs and arms known as "charleyhorse, the condition has received a place in American medical dictionaries as a recognised word.

THE AUTOMATIC REPRODUCTION OF DOCUMENTS

IN THE LANCET of Jan. 3rd we referred to a new method of *copying documents by photography that has been adopted* by the Bureau of Records in the Borough of Manhattan, New York. Our comment was based upon the apparent reasonableness of the process as described; we had not then seen the result Dr. William H Guilfoy, registrar of records, has now sent us a number of records thus copied, comprising copies of birth, marriage, and death [illegible] his body would in no [illegible] finally, a copy of the page of [illegible] p 51) on which our previous [illegible] copies, the text of which appea[illegible] und, are all clear, and obviou[illegible] error in transcribing.

THE EFFECTIVENESS OF MODERN HEALTH MEASURES.

AN interesting example of [illegible] measures is given in t[illegible] director of health at [illegible] September plague-infected rats [illegible] on Sept 22nd In carrying out antiplague measures in the building a *mummified rat and several plague-infected* [illegible] *on the ground floor* [illegible] of a Chinaman employed in the grocery store who had died suddenly on Sept. 20th, his death having been certified as due to pulmonary tuberculosis, was exhumed. The necropsy clearly disproved tuberculosis and gave indications of possible plague, though owing to the decomposi*tion* the diagnosis of plague could not be biologically [illegible] the flea transmission of plague.

CHICLE

THE modern prevalence of the use of chewing gum in the Western world makes a few details concerning the material of medical interest, for rightly or wrongly different pathological effects have been attributed to it Chewing gum is the product of the chicle tree (*Achras sapota*), which is indigenous in the States of Yucatan, Campeche, Tabasco, Chiapas, Vera Cruz, Oaxaca, Puebla, [illegible] and the Territories of Tepic and [illegible] s wild state the tree is [illegible] growing to a height of from 40 to 50 feet. A tree 25 years old, producing 20 to 25 pounds of chicle annually, will measure 25 to 30 feet in height and 22 inches in diameter. When eight to ten years old, and from 12 to 15 inches in diameter, the trees will yield from 5 to 6 pounds. The wood is reddish in colour, resembling mahogany in texture and grain. Prehistoric door-frames and rafters of this wood are found among the Mexican ruins to-day and are still in an excellent state of preservation. The trees are tapped throughout the rainy season by a V-shaped incision encircling the tree. The sap has a milk-white appearance as it flows from the tree, but afterwards becomes yellow, and thickens till it is about the same consistency as treacle. After collection the sap is carried to the boiling-sheds, where it is reduced to the proper consistency. During this operation it is necessary to knead the mass from time to time in order to drive off the water, when it should become lightish-grey in colour, although the exact shade varies according to the different districts of origin. The chicle is almost exclusively exported to the United States, where it is made into chewing-gum, and, according to the Mexican Year-book published in Mexico City, New York, and London (McCorquodale and Co., Limited), about 600,000 kilogrammes are exported to British Honduras, 870,000 kilogrammes to Canada, 1,700,000 to the United States, and only a few hundreds of kilogrammes to other countries.

THE SPREADING OF SCARLET FEVER.

AT Hitchin petty sessions recently a woman named Boyier was convicted upon a summons charging her with allowing her daughter, when suffering from scarlet fever, to be exposed without taking proper precautions against infection. The Hitchin rural district council were the prosecutors. In the locality where the girl lived there had been an outbreak of scarlet fever in November, followed by another early in January, and in the course of inquiries the girl mentioned was found in a peeling condition engaged upon ironing, having been excluded from school that day on account of her state. She had been playing a short time before with other children known to be infected and had recently been to a Sunday-school treat. Her father was employed in the milk trade. The mother declared that she did not know that her daughter had suffered from anything more than a cold. The bench seem to have come to the conclusion that the mother was negligent, but their decision as to her guilt was couched in somewhat ambiguous terms, the chairman being reported as saying that if the defendant did not know the nature of the disease she ought, as a mother of children, to have known. They would convict her, but as the local authority did not ask for a heavy penalty none would be inflicted. The bench wished, however, to caution her severely as to the future, and also wished others to know that they must not expose a patient suffering from scarlet fever.

THE "QUIDOS" CORK SANITARY CUSHION.

Mr. Leoline Edwards, of 81, St. Margarets-road, Twickenham, has sent us a specimen of a cushion seat for which he claims sanitary advantages. The seat is made of two pieces of green "rot-proof" canvas sewn together and filled with granulated "Quidos" cork. The canvas is sewn across in six parallel divisions, each division being filled with broken cork. This filling is non-conducting, and can be washed or disinfected by steam or heat without injury. The material, which is also used for mattresses and chairs, is very cleanly, and there can be no excuse for not keeping the cushion clean, since this can be done without spoiling the fabric.

AN ELASTIC TRUSS.

WE are asked by Mr. John Dee Shapland, M.R.C.S., of Exmouth, to say that the truss mentioned in THE LANCET of last week is made by Brook's Appliance Company, Bank Building, Kingsway, London, W.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Discussion: The Constitution of the Atom (opened by Sir Ernest Rutherford).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries: W. Langdon Brown, Philip Hamill): at 4.30 P.M.

Paper:

Dr. G. C. Low: The Therapeutic Uses of Emetine.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart C. Price-Jones): at 8.30 P.M.

Dr. J. F. Gaskell: The Lesions of the Kidney in Ulcerative Endocarditis.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—J. M. H. MacLeod, S. E. Dore): at 4.30 P.M.

Cases:

Dr. Pernet: (1) Multiple Lupus Vulgaris; (2) Angioma Serpiginosum.

Dr. S. E. Dore: Multiple Subcutaneous Fibromata.

Dr. Norman Meachen: Persistent Erythema.

Dr. A. M. H. Gray: (1) Chronic Erythematous Eruption; (2) Acne Agminata with Bilateral Enlargement of Lachrymal Glands; (3) Recurrent Bullous Eruption of Legs.

And other Cases.

FRIDAY.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—Cecil R. C. Lyster, S. Gilbert Scott): at 8.30 P.M.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Demonstration of Pathological Specimens. Private Cases sent for Consultation. Clinical Cases will be shown by Dr. M. Dockrell, Dr. Bunch, Dr. Sibley, Dr. Phibbs, Dr. Gooding, and Dr. Griffith. 5.15 P.M., Paper:—Dr. Bremner (Leicester): The Frontiers of Dermatology.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Paper:—Mr. R. Burrows: Must a Prison Governor Keep Prisoners not Merely Safe, but Safe and Sound?

CHELSEA CLINICAL SOCIETY, Club Rooms of the Medical School, St. George's Hospital, S.W.

TUESDAY.—8.30 P.M., Annual Clinical Debate on Arteriosclerosis. Paper:—Dr. L. Williams: Arteriosclerosis. Followed by a discussion in which Dr. Langdon Brown, Dr. C. Thomson, Dr. Furber, Dr. H. Dally, and others will take part.

BRITISH OTO-LARYNGOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

WEDNESDAY.—4 P.M., Epidiascope Demonstration.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—8 P.M., Mr. E. H. Ross: House Flies and Disease.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Goulstonian Lecture:—Dr. M. A. Cassidy: Rheumatoid Arthritis. (Lecture III.)

THURSDAY.—5 P.M. Lumleian Lecture: Dr. J. A. Ormerod: Some Modern Theories concerning Hysteria. (Lecture I.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies street, W.C.

MONDAY.—4 P.M., Dr. J. L. Bunch: Clinique (Skin). 5.15 P.M., Lecture:—Dr. A. J. Jex-Blake: The Nervous Complications of Diseases of the Chest.

TUESDAY.—4 P.M., Dr. R. H. Miller: Clinique (Medical). 5.15 P.M., Lecture:—Dr. S. A. Owen: The Clinical Significance of Enlargement of the Liver and Spleen in Infancy and Childhood.

WEDNESDAY.—4 P.M., Mr. G. Taylor: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. W. Carmalt Jones: The Classification of Arthritis.

THURSDAY.—4 P.M., Dr. G. Holmes: Clinique (Medical). 5.15 P.M., Lecture:—Dr. R. W. Allen: The Rôle and Scope of Vaccine Therapeutics in Medicine.

FRIDAY.—4 P.M., Mr. J. G. French: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Page: Spinal Anæsthesia.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Bernstein.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. 11 A.M., Dr. Davis: Operations of the Throat, Nose, and Ear. 12 noon, Mr. Souttar: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Page: General Anæsthesia.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months ..	0 12 6	Six Months	0 14 0
Three Months .	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

Sciences, &c

Communications, Letters, &c., have been received from—

A.—Mr. W. Alabaster, Lond.; Dr. F. S. Arnold, Bovingdon; Mr. P. H. Adams, Oxford; Messrs. Arnold and Sons, Lond.; Dr. Adamson, Lond.; Mr. F. Aldridge, Lond.

B.—Messrs. H. B. Barnard and Sons, Lond.; Professor Dr. L. Brauer, Hamburg; Barnstaple, Medical Officer of Health of; British Anti-Tobacco and Anti-Narcotic League, Manchester, General Secretary of; Messrs. Butterworth and Co., Lond.; Dr. W. Broughton-Alcock, Paris; Dr. J. Blumfeld, Lond.; Mr. R. E. B. Beal, Lond.; Mr. H. W. Bayly, Lond.; Mr. R. Bishan, Nowgong; British Alizarine Co., Lond.; Messrs. Bayer Co., Lond.; Bolton Education Committee, Director of; Dr. C. Burnham, Hemel Hempsted; Mr. T. S. Brooke, Hemel Hempsted; Mr. R. St. Leger Brockman, Lond.; Captain J. A. Bennett, R.A.M.C., Eastbourne; Mr. H. A. Berens, Lond.; Dr. S. H. Belfrage, Lond.; [illegible], Lond.; [illegible] Hos[illegible] Diseases, Secretary of; Messrs. W. H. Bailey and Son, Lond.; Messrs. Burroughs Wellcome and Co., Lond.; Birkenhead and Wirral Children's Hospital, Hon. Secretary of; Dr. Charles A. Bucklin, Glasgow; British and Foreign Blind Association, Lond.; Mr. E. Buckman, Cheltenham.

C.—Dr. Lewis Gregory Cole, New York; Mr. Wilfrid H. Coltart, Oswestry; Dr. F. C. Coley, Newcastle-on-Tyne; Colombo, Medical Officer of Health of; Dr. F. R. Cross, Clifton; Dr. R. Carswell, Lond.; Dr. J. Basil Cook, Isleworth; Messrs. Cookes and Southorn, Leamington; Mr. H. A. Collins, Croydon; Messrs. Corbyn, Stacey, and Co., Lond.; Messrs. E. Cook and Co., Lond.; Central London Throat and Ear Hospital, Secretary of; Casein, Ltd., Lond.; Dr. D. Corbett, Lond.; Chirurgische Universitats Klinik, Kyoto; Messrs. J. and A. Churchill, Lond.; Camberwell Guardians, Clerk to the; Chesterfield Hospital and Dispensary, Secretary of; Cossham Memorial Hospital, Bristol, Secretary of; Mr. A. H. Cutler, Lond.; Mr. Chas. D. Clayton, Lond.; Mr. J. Cloustie, New Malden; Dr. R. Colvin-Smith, Cromer.

D.—Dr. V. T. Dickinson, Lond.; Dr. Leigh Day, Colchester; Messrs. W. Dawson and Sons, Lond.; Dorset County Hospital, Dorchester, Secretary of; Durham County Council, Clerk to the; Dorland Agency, Lond.; Sir Bryan Donkin, Lond.; Mr. John Dover, Totland Bay; Sir Bertrand Dawson, Lond.

E.—Miss Lesbia Edwards, Lond.; Mrs. W. R. Elzholz, Berlin; Dr. A. R. Eates, Lond.; Mr. R. H. Elliot, Lond.; East Suffolk Hospital, Ipswich, Secretary of; Dr. G. Efremoff, Gara Kaliste; E. J. S.; Dr. Alfred Eddowes, Lond.

F.—Dr. S. Fouracre, Lond.; Mr. B. Fletcher, Lond.; F. W. U.; Mr. H. Frohnhaeuser, Heidelberg; Messrs. Fannin and Co., Dublin; Messrs. Ferris and Co., Bristol; Farnham House, Finglas, Secretary of; Dr. C. M. Fauntleroy, Honolulu; Messrs. F. H. Faulding and Co., Lond.

G.—Dr. W. C. Gordon-Keats, Mineapolis; Messrs. Gonzalez, Byass and Co., Oporto; Mr. A. Guzman, Valladolid; *Gazette Médicale de Paris*, Manager of; Messrs. W. and A. Gilbey, Lond.; Mr. F. Gill, Sheffield; Mr. J. B. Graham, Belfast; Dr. W. S. Gregory, St. Joseph.

H.—Mr. R. J. Hutchinson, Haslemere; Dr. G. Heath, Leicester; Mr. K. G. Hearne, Salisbury; Hoffmann-La Roche Chemical Works, Lond.; Messrs. Hankinson and Son, Bournemouth; *The Hospital*, Lond., Manager of; Mr. P. Harper, Lond.; Messrs. P. Harris and Co., Birmingham; Dr. W. P. Herringham, Lond.; Dr. Otto Holst, Eastbourne.

I.—Illuminating Engineering Society, Lond.

J.—Dr. F. Wood Jones, Lond.; Dr. H. Lewis Jones, Lond.; Dr. Alfred C. Jordan, Lond.

K.—Dr. Oscar Kraus, Lond.; Messrs. Kutnow and Co., Lond.; Messrs. H. S. King and Co., Lond.; Mr. W. B. Kebble, Lond.; King Edward's Hospital Fund for London, Hon. Secretaries of; Kenny Advertising Agency, Dublin.

L.—Mr. James Little, Melbourne; Dr. R. Lee, West Drayton; Dr. P. W. Latham, Lond.; Mr. M. Lall, Abigarh; Dr. G. Stirling Landon, Perth; Messrs. E. and S. Livingstone, Edinburgh; Liverpool Corporation, Clerk to the; Mr. H. K. Lewis, Lond.; Messrs. Lee and Martin, Birmingham; Leicester Corporation, Medical Officer of Health of; Messrs. Lee and Nightingale, Liverpool.

M.—Dr. Alfred A. Mumford, Manchester; Medical Society of London, Registrar of; Messrs. Marcus and Weber, Berlin; Mr. F. J. McCulloch, Lond.; Mendip Hills Sanatorium Wells, Secretary of; Colonel T. J. McGann, Mysore; Dr. A. McKenzie, Durban; Dr. F. E. Meths, Trieste; Mr. K. V. G. Menon, Tellicherry; Mr. J. F. [illegible] Mr. J. [illegible] Maltine [illegible] Lond.; [illegible] Mr. H. [illegible] chester Royal Infirmary, Secretary of; Mr. R. Mosse, Berlin; Dr. S. R. Macphail, Rowditch; Dr. Reginald Morton, Lond.; Mr. R. D. Mothersole, Bolton; Dr. J. A. C. Macewen, Glasgow; [illegible] Bath.

N.—Dr. Edwin H. Nash, Wimbledon; Norwich Corporation, Town Clerk of; National Dental Hospital and College, Lond., Secretary of; Dr. A. Neve, Kashmir; Dr. H. F. G. Nye, Worthing; Dr. John Nach Noyes, Lond.

O.—Optical Convention, Lond., Hon. Secretary of; Messrs. Osborne Peacock Co., Manchester; Messrs. C. Oppel and Co., Lond.; The Oakland Motor Car Co., Lond.

P.—Dr. Owen Paget, Fremantle; Parathalassa; Mr. F. J. Pack, Salt Lake City; Messrs. Parke, Davis, and Co., Lond.; Prestwich County Asylum, Manchester, Medical Superintendent of; Dr. Charles A. Parker, Lond.; Mr. A. Phillips, Liverpool.

Q.—Queen's Hospital for Women, Lond., Secretary of.

R.—Dr. A. H. S. Roberts, Portsmouth; Mr. Herbert Rhys, Lond.; Royal Hospital for Diseases of the Chest, Lond., Dean of; Royal Victoria Hospital, Montreal, Secretary of; Royal Ear Hospital, Lond., Secretary of; Messrs. Reynell and Son, Lond.; Dr. C. H. G. Ramsbottom, Aldeburgh; R. O.; Royal Infirmary, Hull, Secretary of; Royal Portsmouth Hospital, Secretary of; Mr. J. Reid, Edinburgh.

S.—Mr. J. Shirlaw, Lond.; Dr. Alexander Stookes, Liverpool; Dr. W. Mitchell Smith, Tean; Colonel Smith, Stafford; Messrs. Spottiswoode and Co., Lond.; Dr. W. T. Scott, Banchory; Mr. Sewill, Red Hill; Mr. P. Schmidt, Basle; Mr. J. Smith, Lond.; Messrs. Spiers and Pond, Lond.; Mr. T. Shennan, Edinburgh; Surrey Lunatic Asylums Committee, Kingston-on-Thames, Clerk to the; Salford Royal Hospital, Secretary of; Sunderland Royal Infirmary, Secretary of; Messrs. G. Street and Co., Lond.; Mr. J. Dee Shapland, Exmouth; St. Paul's Hospital, Lond.; Southport Infirmary, Secretary of; Dr. W. Fletcher Shaw, Manchester.

T.—Messrs. W. Thacker and Co., Lond.; Dr. W. W. Thom, Boulogne-sur-Mer; Mr. Leslie B. C. Trotter, Ledbury; Dr. Francis H. Thiele, Lond.; Dr. John Tatham, Old Oxtead.

U.—Messrs. Urban and Schwarzenberg, Vienna; Under-Secretary of State for the Colonies, Lond.

W.—Professor David Waterston, Lond.; Dr. F. W. Ainley Walker, Oxford; Woodhall Spa Co., Woodhall Spa, Secretary of; Mr. J. W. Walker, Wakefield, Dr. Tucker Wise, Montreux; Messrs. A. J. Wilson and Co., Lond.; Messrs. Wills, Lond.; West Herts Hospital, Hemel Hempsted, Secretary of; West Riding Asylum, Burley-in-Wharfedale; W. D. D.; Messrs. Widenmann, Broicher, and Co., Lond.; Mr. A. Wilson, Lond.; *Wolverhampton and Midland Counties Herald*, Secretary of; Dr. J. A. Watson, Dublin; West Riding County Council, Wakefield, Clerk to the; Mr. M. J. Wunderlich, Guatemala; West Ham and Eastern General Hospital, Lond., Secretary of; Dr. A. L. Whitehead, Leeds; Dr. S. A. K. Wilson, Lond.; Dr. J. H. Wilson, Standish; Mr. W. H. P. Woodcock, Lond.

Z.—*Mr. Carl Zeiss, Lond.*

Letters, each with enclosure, are also acknowledged from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. J. Atlee, Lond.; Mr. A. Alexander, Tadley; Dr. M. B. Andrews, Belfast; Anglo-American Pharmaceutical Co., Croydon; A. F. C.; Ashwood House, Kingswinford, Secretary of.

B.—Dr. A. H. Bizarro, Lisbon; Dr. N. Bradley, Crowborough; Messrs. Briant and Sons, Lond.; Lady Maud G. Barrett, Rushington; Dr. J. H. Bartlett, Lavant; Mr. W. H. Barrett, Chichester; Brentford Union, Lond., Clerk to the; Birmingham Corporation, Clerk to the.

W.—Mr. H. R. Walker, Torquay; [illegible] County Council, [illegible] to the; [illegible]bledon Corporation, Treasurer to the; Mr. B. Wheeler, Manchester; Messrs. F. Williams and Co., Lond.; Dr. C. E. Wilmot, Ramsey; Dr. R. J. Willan, Newcastle-on- [illegible] Co., [illegible] Secretary of.

Y.—Mr. M. Yearsley, Lond.

Hunterian Lecture

ON

THE BIOLOGY OF TUMOURS.

Delivered before the Royal College of Surgeons of England on March 9th, 1914,

By C. MANSELL MOULLIN, M.A.,
M.D. Oxon., F.R.C.S. Eng.,
HUNTERIAN PROFESSOR; CONSULTING SURGEON TO THE LONDON HOSPITAL.

Mr. President, Fellows and Members of the College,—In the Bradshaw lecture which I had the honour of delivering before this College in November, 1912,[1] I endeavoured to show that the problem that underlies the biology of tumours is not the nature of the force that makes tumours grow, for growth, ceaseless, continuous growth, is a property innate in all living tissues, whether they form part of a tumour or not, but the nature of the force that can suddenly, at some particular spot, bring development to a standstill and liberate this innate power of growth so that the tissues increase and multiply as they will, free from all control. To-day I hope to be able to show that the action of this force can, in some instances at any rate, be traced back to interference with the chemical changes in the tissues upon which their development depends, and that the causes that give rise to this interference must be regarded as essential factors in the production of tumours.

The Influence of Development Over Growth and Reproduction.

Growth is part of the life of living things, and reproduction is only growth beyond the individual. The power of growth and reproduction is born in all living things with their birth, lives with them throughout their lives, and dies with them when they die. In the primitive forms of life this power knows no bounds. External conditions such as temperature and the supply of food are the only check upon it. But as development progresses and becomes more complex, the capacity for growth and reproduction diminishes, until at last, when the higher grades of specialisation are reached, the power of reproduction is all but lost, and even that of growth is greatly restricted.

The story of the race is an illustration of the way in which the progress of development deprives the primitive power of growth and reproduction of all its capabilities, one after the other. The first to disappear is the power of forming germs for the reproduction of the race. In the earliest forms of animal life this is common to the whole organism. Very soon it becomes limited to one small segment, which is specialised for this alone, and is lost to all the rest. The next is the power of forming buds able to reproduce the individual—a power still retained by such organisms as marine worms. A little later this is followed by the power of reproducing organs and limbs, though this still exists in a limited way even in animals so highly organised as reptiles. At last, all that is left of the original almost unlimited power is the ability to reproduce simple structures such as tissues. Throughout the history of the race, beginning from the earliest times, step by step as organisation advances and development becomes more complex the primitive power of growth and reproduction becomes more and more restricted.

What is true of the history of the race is no less true of the history of the individual. In the earliest moments of existence the power of growth and reproduction is almost unbounded, and is shared by all parts of the embryo alike. The first step is the differentiation of the germ cells from the rest which from that moment cease to have any direct concern with the maintenance of the race. The ability to throw off buds that can grow into organisms like the parent disappears almost at the same time; then the power of reproducing portions of the body such as limbs and organs. In a little while all that is left to the somatic cells of the almost unlimited capacity they once possessed is the power to reproduce tissues—highly complex ones—in early embryonic life, only those that are comparatively simple in adult years. And at last when specialisation has reached its highest point, as in the organs of special sense, even this is no longer possible. The power of growth remains, but not that of reproduction. As the tissues become better and better adapted to their own special work, and as their differentiation advances, they lose the ability to perform the general duties that once were common to them all, and with it their birthright, the power to grow and reproduce their kind. Growth and reproduction become more and more limited as development advances.

Tumours Formed by Gemmation, not by Fission.

Tumours originate as buds, by a process of gemmation, from tissues that are apparently normal. Structures formed by fission or division are not tumours in the same sense of the term. Unless prevented by mechanical conditions the parts into which they divide develop equally. A fertilised ovum, for example, or in the case of unicellular reproduction, a bud that has just been detached from the parent organism, may increase in size so fast that any slight accident or movement is enough to cause the primary segments to separate from each other. If the separation is complete and the other conditions are favourable, two distinct organisms are produced, resembling each other so closely that even late in life they cannot always be distinguished, as in the well known instance of the two poachers who, although they had been convicted, one it is believed 39 times and the other 53, were yet a hopeless puzzle to the village constable and the bench. If the separation is incomplete the result is one of those double monstrosities so common in our museums, which sometimes are born alive and even reach old age. The same thing is true of bifid limbs and other organs. They originate in the same way, at a later stage, as the products of overgrowth of normal structures or of too rapid growth. Sometimes, when one part is developed fully and the other remains stunted and atrophied. it is not easy to recognise the relation they bear to each other, but, as Bland-Sutton has pointed out, their origin can always be ascertained by their similarity at the point of division. Structures such as these should be placed in a class by themselves. They differ from what are commonly called tumours in one essential particular—there is no arrest of development except such as may be caused by pressure or other mechanical causes.

Of the Different Kinds of Tumours.

Buds that grow out from normal tissues and form tumours always develop along the same line as the parent stock, but never reach a higher stage and reached maturity will grow into a malignant one if it is still in the embryonic stage. Every innocent tumour has its counterpart among malignant growths. Innocent and malignant spring alike from the same cells, but in the one case the parent has already reached, or nearly reached, maturity, for it is doubtful if fully mature cells ever form tumours; in the other it is still in the embryonic stage, with all the embryonic vigour of growth unimpaired.

---

[1] The Lancet, Dec. 7th, 1912, p. 1567.

Sarcoma and carcinoma are artificial groups, not natural ones. It is not possible to define or limit either of them. Because all cells resemble each other in their embryonic stage, regardless of locality or future destiny, the tumours that spring from them at this stage naturally resemble each other too, for the tumour cell never advances in development beyond the point the parent has reached at the moment of its birth. For this reason, because there is this superficial resemblance, all tumours springing from embryonic tissues, or tissues resembling them, have hitherto been grouped together under one or other of these names. But there are great differences in the potentialities of these tumour cells, though they may appear to be so much alike, because there are great differences in the potentialities of the cells from which they spring, and the tumours show these differences if they are looked for. The cancer of one organ is entirely different from the cancer of every other organ, and the clinical history of periosteal sarcoma varies with the bone to which the periosteum belongs. Each organ and each tissue has its own variety of malignant tumour, just as it has its own variety of innocent tumour, though the microscope may be unable to distinguish them, and the innocent tumours of each organ shade off by imperceptible stages into the malignant ones, so that together they form one group. No line can be drawn between them. The structure of a tumour depends upon that of the parent tissue; its character, whether it will be innocent or malignant, depends upon the degree of maturity of the cell that gives off the bud.

FEATURES COMMON TO ALL TUMOURS.

There are certain features common to all tumours. They become much more common as the tissues grow old. They occur most frequently in parts of the body that are liable to be irritated, in which, therefore, young growing cells are always abundant. Their size continues to increase as long as they can get supplies. Their development never advances. It never surpasses that of the parent at the moment that the bud was formed, and seldom equals it. Their individuality is their own, and they yield no obedience to the laws that govern the growth and development of the host on which they live. They are, in other words, buds that have grown beyond the individual, products of that power of asexual reproduction which is the birthright of all the tissues.

The problem of the biology of tumours turns upon the question why one particular cell, or group of cells, suddenly ceases to develop, ceases to advance along the lines laid down for it in the past, and, instead, makes use of all that it still retains of its primitive power of growth and reproduction to give birth to what is to all intents and purposes another individual. What, in other words, is the reason why development comes to a standstill, and the growth of the individual cell, or group of cells, is suddenly given up for growth beyond the individual?

THE EFFECT OF INTERFERING WITH THE CHEMISTRY OF THE TISSUES.

Growth and development are both the outcome of the chemical changes that take place in living tissues—the changes upon which their life depends. This is acknowledged in the case of growth. Foreign substances come into contact with a living cell. They are absorbed by it and broken up in it by catalytic agents. The products of this catalysis are built up again in a different combination, and if the addition exceeds the consumption the result is, first, increase in size, and then, if circumstances are favourable, increase in number, each newly formed cell possessing the same power as the parent of which it once was part.

The same thing is true of development. Development, like growth, is the outcome of chemical changes that take place in the living cell, but with this difference, that while growth depends upon the maintenance of all the reactions in their relative proportions, development depends upon the predominance of one. Development is the result of one of these chemical reactions, or rather of one series of them, being carried on in excess of all the rest for generation after generation. Division of labour means that every part of the body has to undertake a special kind of work. Special work entails a special chemical reaction or series of reactions. The more thoroughly the work is done, the more completely does this special reaction predominate over all the others at that particular spot. This, continued in the same group of cells for generation after generation, of necessity involves progressive modification of chemical constitution and of structure, or, in other words, development.

The layer of cells, for example, on the exterior of the organism, always exposed to foreign influences, becomes modified in course of time. They become harder and more resistant. Keratin or some similar substance forms in them, and as generation succeeds generation and a similar modification takes place in each, at last an outer protecting layer is developed characteristic of that particular kind of organism. The same thing is true of the cells that line the digestive tract. Their special work, or one part of it, is the manufacture and discharge of catalytic ferments. The chemical reactions upon which their working depends have been gradually evolved in the course of ages from simpler ones of the same kind. According to Twort and others the process of chemical evolution is still going on. New ferments are being formed, even at the present time, to deal with new conditions, and structure and arrangement are modified accordingly. So it is with other tissues and other parts of the body—those, for example, that are concerned with the transmission of impulses from one organ to another. Special work involves the evolution of special chemical reactions; and as generation succeeds generation and the reactions become better adapted to the end in view, the structure and arrangement of the part become modified to suit. Development, in other words, is the outcome of the persistent cultivation of a special series of chemical actions, necessitated by the special work the part has been called upon to do.

If these chemical changes are interrupted at any point before the reaction is completed; if, for example, some essential factor fails to be supplied at the right moment, or an unnecessary one is introduced, the special work that depends upon that reaction is brought to an immediate standstill; differentiation ceases with it, and no matter at what stage it may be, whether it is nearly completed or only just beginning, development comes to an end. Growth, on the other hand, because it is not concerned in the least with this special reaction, continues as before, but with all the conditions changed. The native power of asexual reproduction, which is kept under control so long as development is progressing, is now set free in its full strength, and the result is a tumour—a growth that reproduces more or less accurately the structure of the parent tissue, whatever it may be at the moment, with an individuality of its own, incapable of higher development, for the special chemical reaction upon which development depends is broken off, but capable of increasing in size so long as it can draw supplies.

The Production and the Disappearance of Tumours.

So little is known of the intimate nature of the chemical changes that take place in the tissues that it is not easy to cite instances in which the failure of any particular one has led directly to the cessation of development and the production of a tumour. There are, however, many isolated facts that point in this direction. One of these relates to the occasional disappearance of tumours. It is well known that tumours, especially those of an embryonic type, sometimes stop growing, diminish in size, and even disappear under the influence of remedies which can only act through the medium of the general nutrition. Carcinoma of the breast, for example, has been known to shrink in size and even to disappear after oophorectomy. The same thing occasionally happens without special treatment of any kind, perhaps more frequently than is usually believed. At least it is difficult in any other way to account for the single successes of weird remedies which are recorded from time to time, apparently in perfect good faith, and which can never be repeated. In the case of most of these it is not possible to say how or by what means the remedy acts; but in some it is almost certain that the effect is due to the reagent entering into chemical combination with the living substance of the tumour cells. Arsenic, for instance, administered internally sometimes causes lymphadenomatous growths to recede and almost disappear. Then, only too often, after a little while the growth begins to increase in size again, and now the same drug, even in far larger doses, has absolutely no effect. The same thing is true of Coley's toxins in cases of sarcoma. It is not uncommon to find that a sarcomatous growth diminishes greatly in size after a few injections, without disappearing altogether, and then starts growing again in a form that is absolutely resistant even to much larger quantities. The tumour cells, in other words, have acquired immunity and have become arsenic-fast or toxin-fast, as the case may be, just as Ehrlich has shown the spirochæta can, and for the same reason—the drug has entered into chemical combination with some element in the substance of the growing cell.

Another of these facts, in many ways even more striking, relates to the production of tumours. It is generally admitted that the continued employment of certain substances, in industry as well as in medicine, is liable to be followed by the growth of certain kinds of tumours. The substances themselves are not the immediate cause of the growth. There is often an interval of years between their administration and the appearance of the tumour. But they initiate such changes in the nutrition of the tissues that when irritation of any kind, whether it is mechanical or chemical or due to the action of living organisms, leads to the rapid production of a large number of young cells, some of these cells fail to develop as they otherwise would, and form the basis from which a tumour grows. This has long been known in connexion with arsenic. The late Sir Jonathan Hutchinson was the first to lay emphasis upon the fact that the prolonged internal administration of arsenic sometimes led to the development of multiple epitheliomata. The nutrition of the skin becomes affected; its texture becomes altered, and then, at some spot where continued irritation leads to the rapid production of a number of young cells, epithelioma develops.

A closely similar course of events has been described in connexion with some of the anilin dyes, only in this case the tumours do not involve the skin but the urinary organs, and assume different forms according to their origin. Rehn in 1906 had already collected more than 30 cases of workers in fuchsin who were suffering from some form of tumour of the bladder. Leuenberger has collected many more, and has shown that in Basle the deaths caused by tumours of the bladder in the years 1901–10 were 33 times more common among the workers in anilin colours and similar substances than they were among the rest of the male population; and that more than half of the cases of tumour of the bladder observed in the last 50 years in the male surgical clinic at Basle came from dyers and those engaged in anilin dye works. In the majority of the cases observed by Leuenberger himself the growth was a carcinoma, but in some it was a sarcoma and in others it was mixed. Some grew in the bladder, others in the kidney and ureter; and what is of peculiar significance, in some instances the growths did not make their appearance, or at least cause symptoms, until years after the worker had left his employment. A similar condition of things has been recorded of the workers in the cobalt mines of the Schneeberg, only in this case the growths which are equally varied in their character are met with in the lungs. The papillomata and other tumours that so often follow the continued application to the skin of soot, tar, paraffin, and the like, arise in a similar manner. Some substance is absorbed and affects the nutrition and the functional activity of the skin, so that it becomes harsh and dry. The cells no longer carry on their special work as they should. Their development, which depends upon their work, ceases to advance. The power of growth and asexual reproduction, on the other hand, which is theirs so long as they are living, and which does not depend upon any special reaction, is not affected. The result is an unlimited multiplication of cells the degree of whose development depends upon that of the parent stock at the moment. If the affected cells have all but reached perfection before the interference is felt, the buds that grow from them are all but perfect too. The tumour is composed of tissues that resemble those of the normal skin. But if owing to irritation, whether it is mechanical or chemical, or due to the action of living organisms, there is a great increase in the proportion of young rapidly growing cells, and the development of these is checked, the buds that spring from them [illegible] th[illegible] [illegible] th.

growth increases rapidly in size and spreads wherever it can.

Facts such as these, it seems to me, admit of but one explanation. Tumours, no matter what their clinical character may be, are caused by the sudden escape from control of the innate power of asexual reproduction present in some measure in all tissues as part of their life. So long as development is advancing, growth and reproduction are under control. But development depends upon special work, and work in its turn depends upon the special chemical reactions which have been evolved in the course of ages and are still being evolved. If these reactions are interfered with, whether by the addition of strange elements or the failure to supply necessary ones, work comes to an end; development stops with it; and the power of growth and reproduction, or that measure of it which the tissues possess at the moment, is set free without limit, except in so far as supplies are concerned, and without control.

In the illustrations I have given the interference with the nutrition and the chemical reactions of the tissues has been caused by the slow continuous working of substances introduced into the body from without. Some have entered through the digestive tract, others through the lungs, and others again through the skin. It does not seem to me unwarrantable to assume that a similar interference can be caused by substances produced in the body itself, more especially as age advances. It need not necessarily be at the place from which the tumour grows. It may be at some distant spot from which the substance is carried by the blood stream, as it is, for example, in the case of arsenic. It may be some minute difference in one of the constituent elements of which we are as yet incapable of judging, or there may be an additional one introduced, or some essential one may fail at the moment it is wanted. Whatever it is, this I venture to say is the direction in which we are to look for the next great advance in the biology of tumours, and this is the direction in which investigation should be made.

THE TECHNIQUE OF THE OPERATION OF SCLERO-CORNEAL TREPHINING FOR GLAUCOMA.

BY R. H. ELLIOT, M.D. LOND., F.R.C.S. ENG.,
LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.

WHEN the writer left India the Madras figures showed over 900 trephinings, and the number of surgeons who had learnt to practise this operation there could be counted by tens. Since then he has had the opportunity of trephining 135 eyes in the course of a tour in America, and of performing the same operation on a number of cases in England. In both countries he has had the great advantage of receiving very valuable suggestions from those who attended his demonstrations. The object of this paper is to place the experience so gained at the disposal of others.

1. *In which quadrant of the eye should the trephine be applied?*—It is obvious that under most circumstances the upper is the quadrant of choice, for (1) the wound is then less exposed to infection; (2) the iridectomy, if one is performed, lies under cover of the lid; (3) the conjunctival flap rarely requires a stitch when made above; and (4) the measurement from the angle of the anterior chamber to the limbus, and consequently the space available for the implantation of a trephine, is greatest above. It is not, however, possible to trephine above the cornea in all cases, and it is inconvenient to do so in some others—viz., (1) when a patient is troublesome, and looks obstinately upward; (2) when the operation is undertaken for the relief of staphyloma, and the upper part of the cornea is involved in the swelling; (3) when, in chronic cases, it is obvious that the chamber is shallower in an upward direction than elsewhere; and (4) when a condition similar to the last named is due to anterior synechia, accompanied by rise of tension.

2. *The nature of the flap and the method of making it.*—In making the conjunctival flap one should avoid the brow with the scissors; if this be not done the eyebrows will be cut and dropped on to the wound, thus soiling it.

(i.) *The incision.*—The conjunctiva should be seized as high up as possible on the bulb with forceps, and drawn well down, at the same time asking the patient to look strongly downward; one free cut in the direction in which the flap is to be made, followed by a couple of snips at each side, will often outline the flap throughout its extent. The incision we now employ runs roughly concentric with the limbus, and ends on either side opposite the highest point of the cornea, and about 8 mm. to its inner and outer sides.

(ii.) *The dissection of the flap.—It is unnecessary, and therefore unsurgical, to dissect up the whole area included in the flap;* moreover, by so doing we rob the flap of the check-ligament-like action of the connective tissue at the angles of the wound. If we leave this tissue intact, the detached conjunctiva tends to spring back into place when released from the downward pull, whilst if we clear the margins of our wound we find that at the end of the operation the flap falls limp and inert over the cornea like a loose apron. We should for this reason carry our dissection down to the limbus over the central area only. Such a procedure does not in the least prevent us from exposing the part we require for trephining, whilst it helps very materially to make our flap lie in good position when the operation is finished, and so often enables us to dispense with the use of a suture. In the upper portion of the dissection we do not need to take up anything but the loose conjunctiva. *As we approach the limbus we should work down to the sclera, and should expose the latter bare in the last few millimetres of the wound.* At the same time the breadth of the dissection should contract as we approach the cornea, so that when we reach the latter we only expose just such a breadth of it as we mean to split, and very little more. Our *next landmark is the limbus, and we must clearly define this* as a rounded ridge slightly overhanging the adjacent sclera. A failure to do so involves a considerable risk of difficulty when we come to split the cornea in the next stage of the operation. *The area over which we are about to apply the trephine must be carefully cleared of all tags of loose tissue;* if this precaution is neglected, the trephine will not bite well, and will tend to shift from its position; moreover, when it does begin to cut, these tags may get caught in the action and tend to draw the flap into the wound and damage it. There is a little knack in getting the sclera clear; this consists in closing the blades of a sharp-pointed scissors (those we have used so far in the operation), and making a number of scraping movements *from the centre of the wound out to each side*, close above the cornea; this manœuvre succeeds in clearing the central area of loose tissue, and so provides a clean surface on which to apply the trephine blade at a later stage of the operation.

(iii.) *The splitting of the cornea.*—It must first be clearly stated that what we desire to do is to *split the cornea* and not to cut it. For this purpose the conjunctival flap should be drawn gently downwards by traction with closed forceps laid on it, and finding counter-pressure against the cornea; it must on no account be seized in the grip of forceps and pulled down therewith, or it may easily be torn and rendered useless for covering the filtration hole. At the same time, the cornea is split with the scissor points, which are kept closed for the purpose; or any other convenient instrument may be employed. The most important point is to *work at exactly the right place*—i.e., just behind the line of reflection of the flap; a number of short lateral strokes along this line speedily effect our purpose in most cases. If the cuts are made too far forwards the flap is at once button-holed, whilst if they are made too far back the surgeon merely wastes his time in an ineffective scratching of the sclera. The instrument is inclined at an acute angle to the cornea, bearing in mind that what we want to do is to peel off the superficial layers in a thin flap. As the dissection proceeds the so-called "dark crescent" of cornea can be seen clearly as a dark area convex in outline towards the sclera, and with a straight edge on the corneal side.

3. *The application of the trephine.*—With increasing experience one thing has become absolutely clear—viz., that if we wish to trephine the chamber and to establish a permanent filtering channel with a minimum of trouble, we have to be careful to place our trephine hole as far forward as possible; the flap should be pulled gently towards the centre of the cornea by traction exerted with the points of the closed forceps, and the trephine placed on the prepared corneo-scleral surface so that its edge will *just clear* the flap, thus making use of every fraction of a millimetre of the area which has been gained by the splitting; the dark crescent of corneal tissue bordering the base of the flap can very easily be seen and defined. The trephine should not be dumped down on the spot on which it is to work, but should be slid into place from the scleral side, the edge of the flap being keenly watched the while; this manœuvre greatly minimises the risk of button-holing the reflected edge. The *exact amount of pressure necessary* can only be learnt by experience. The adoption of the heavier handle which we now use has greatly simplified this part of the technique. No pressure need be used, as the instrument works by its own weight, and consequently the tendency of the fingers to slip down is practically abolished. All the instrument makers who manufacture the author's trephine have been requested to supply in future the heavier weight of handle—viz., one of ½ oz. *The direction in which the blade of the trephine is to be held relative to the corneo-scleral surface* is a matter of great importance. Our object should therefore be to make the blade cut through first on its corneal edge, and in order to ensure this we must slope its handle-end a little towards the patient's feet. The result will be that as soon as the trephine has cut its way through, the disc, hinged on its scleral side, will be pushed upwards and backwards by a bead of iris tissue, prolapsing through the corneal side of the opening. If the manœuvre is correctly carried out this prolapse occurs with great regularity. It is, however, dependent on two factors—(1) the presence of a moderately contracted pupil before the operation is commenced, and (2) the use of a sharp trephine. The next question of importance is *the size of trephine* to use. We have tried all sizes from 3·5 mm. down to 1 mm., and our personal preference is, on the whole, in favour of a 2 mm. instrument. An opening of this size is practically always large enough, whilst a smaller one has this grave disadvantage—that it does not give room for the use of iris forceps and scissors, should the iris happen to be accidentally dragged into the wound and impacted there.

4. *The iridectomy: its nature and the method of performing it.*—An iridectomy should be made, as a routine step, in every trephining operation, simply to avoid the risk of iridic tissue becoming impacted in the trephine aperture during convalescence. It is a common experience that the trephine disc, when cut by hand (as opposed to the use of a mechanical trephine), remains attached at one point to the scleral coat by a narrow hinge. With a little practice it is possible, as indicated in the last section, so to trephine that the hinge is regularly left on the scleral side of our wound. When this is done with a sharp trephine which cuts its way through round a large part of the circumference we find that the iris bulges into the hole as soon as we withdraw the instrument. The appearance of the little white disc, pushed upwards by the small black bead of iris is characteristic, and it is an easy matter to include both disc and iris in one grip of the forceps and to divide both together with a single snip of the scissor points, thus performing our iridectomy with the same cut that severs the hinge. The great advantage of this is that our grip of the disc steadies the eye and effectively prevents even a troublesome patient from rotating it until after the portion of iris has been removed. We are thus enabled to avoid all risk of the uveal tissue being dragged into and becoming impacted in the trephine hole. When the prolapse is free and large, it is necessary to avoid seizing the whole of it in the forceps grip; it is not difficult to lay hold of just so much of it as lies near the disc—i.e., the peripheral portion only—and we thus obtain a marginal button-hole coloboma.

Having satisfied ourselves that the iris is well returned we next replace the conjunctival flap in good position, by first laying it back over the raw surface from which it was dissected up, and then stroking it well into place with the aid of a spoon or of some similar rounded and blunt instrument. If after so doing, the surgeon waits a minute or two, he will soon see whether the flap is going to adhere to its bed or not. If it rapidly becomes stuck down, and if the gap made by the incision in the conjunctiva is easily reduced to very narrow proportions, he can confidently close the eye and dismiss the patient to bed. But if the wound gap is wide, and if the flap shows a tendency to be very easily displaced by slight movements of the globe, it is better to insert a suture at once rather than to risk the inconvenience of having to do so the next day.

The toilette of the wound.—It is most important that the iris should be thoroughly replaced, and that no uveal tags should be left in the wound. For this purpose we use a small irrigator, and placing the nozzle at the entrance of the trephine hole, we direct a bold stream of aseptic saline solution into the chamber; this easily and quickly washes the iris back into place, always provided that it has not been dragged into the wound and impacted there at an earlier stage of the procedure. At the same time the chamber is washed free of any blood which has been effused, thus giving us a clear view of details. Finally, the upper lid is lifted off the eyeball and brought down to meet the lower one, the patient being at the same time told to look up and to close his eyes. Immediately before doing this, however, we gently stroke the cornea toward the trephine hole with a curette, in order to ascertain whether the eyeball is still soft, and whether the escape of aqueous from the chamber is free. Both eyes are then closed with aseptic pads and a bandage.

Instillation of drops.—Our rule is to avoid all instillation immediately after operation unless the pupil shows a tendency towards upward displacement, in which case eserine drops (gr. 4 ad oz. 1) are instilled. On the third day, provided that the tension is down, we drop in a solution of atropine (gr. 4 ad oz. 1) unless the pupil is already widely dilated and active.

Harley-street, W.

ON THE NATURE OF RODENT ULCER:

ITS RELATIONSHIP TO EPITHELIOMA ADENOIDES CYSTICUM OF BROOKE AND TO OTHER TRICHO-EPITHELIOMATA OF BENIGN NÆVOID CHARACTER; ITS DISTINCTION FROM MALIGNANT CARCINOMA.

By H. G. ADAMSON, M.D. Lond., F.R.C.P. Lond.,
PHYSICIAN FOR DISEASES OF THE SKIN AT ST. BARTHOLOMEW'S HOSPITAL.

Rodent ulcer, ever since it was first described by Jacob of Dublin in 1827, has continued to attract great attention in this country. It has been looked upon by most British observers as distinct in its clinical features and in its pathology from other forms of malignant epithelioma of the skin. Continental authorities, with but few exceptions, which include particularly Unna, of Hamburg, and Dubreuilh, of Bordeaux, have not until recent years recognised rodent ulcer as a special type of epithelioma.

Dubreuilh and Auché in 1901, in an important monograph on rodent ulcer,[1] summarise very clearly the history of the differentiation of rodent ulcer from squamous-cell epithelioma in this country. They divide it into three periods. The first period extends from its description by Jacob to Hutchinson's memoir in 1860. During this period the clinical characters of rodent ulcer were discussed and it was separated from "epithelioma" of the face, which invaded the glands and of which the malignancy was obvious. In the next period the differences between the histological characters of rodent ulcer and of squamous-cell epithelioma were considered—it was pointed out that the cells of rodent ulcer were smaller than those of squamous-cell epithelioma, that they were arranged in lobules, and that they did not form horny cell-nests. Rodent ulcer was recognised as an epithelial growth, but was refused the name of "epithelioma," which was reserved for the frankly malignant growths with horny pearls. These ideas reached their climax with the work of Thin in 1886. Then followed a third period in which the origin of the cells of rodent ulcer was investigated by Beadles, Bidwell, Bowlby, Colcott Fox, Paul, Spencer, Norman Walker, Hutchinson, Thin, and Kanthack (and it may be added by Noon). Most observers regarded it as taking origin from the hair follicles or sebaceous glands, though some thought it might arise from sweat glands.

In Germany rodent ulcer was confounded with other varieties of epithelioma of the skin until Unna and Thiersch called attention to the work of English authorities on the subject. Later German writers recognise rodent ulcer as a special type of epithelioma arising in connexion with the hair follicles, and call it tricho-epithelioma. In France the English work was entirely ignored until Dubreuilh wrote on the subject.

The object of this paper is to bring forward evidence in support of the view that rodent ulcer is an affection distinct from true malignant carcinoma and to expand a suggestion which was made by the writer in the Goulstonian lectures in 1912[2] that rodent ulcer belongs to the class of nævoid growths which include adenoma sebaceum and multiple benign cystic epithelioma (or tricho-epithelioma papulosum).

True carcinoma cannot be regarded as a nævoid growth or an awakened embryonic cell-rest in the sense of Cohnheim's theory. It is more readily explained as an unrestrained proliferation of epithelial cells due to [illegible] relationships and of the normal balance of growth between the epithelial and the connective tissue, as the result of previous damage to the skin.

A striking feature in the etiology of squamous cell epithelioma, in contrast to that of rodent ulcer, is that it arises always upon skin or mucous membrane which has been previously damaged by injury or which has been the seat of long-continued local irritation. Among these "precancerous" conditions are scars from burns, old syphilitic scars or the scars of lupus, chronic irritation of the lower lip from pipe-smoking, leucoplakia of the tongue or vulva, the scars of X ray burns, and, perhaps most common of all, the results of chronic dermatitis produced by frequent exposure to sunlight and known as keratosis senilis, sailor's skin or tropical skin. The same may be said of carcinoma, which occurs at the pylorus, in the gall duct or gall bladder, at the cervix uteri, and in the lower part of the bowel. All these parts are liable to chronic inflammation or ulcerations, and carcinoma in these spots is probably consecutive to these conditions. The theory of dormant embryonic masses cannot explain these facts. The formation of carcinoma can be more reasonably attributed to an irregular proliferation of the epithelial cells, as a result of the loss of normal relations between the epidermis and the subjacent tissue. The anatomical balance between different tissues which normally prevents the epithelium from invading the connective tissue is disturbed by damage and partial repair. Disturbance of the anatomical balance is assisted possibly by an upset of the biochemical balance owing to alterations in the nutrition and metabolism of the cells due to age or to the harmful action of agents such as light or X rays.

In sections of keratosis senilis and of X ray scars one may study this gradual disturbance of the balance of growth, beginning with irregular restoration of the epidermis, through warty growths, to the final stage, in which the irregular growths of the epidermis advance completely out of line and invade the spaces between the connective tissue cells. The study of these affections of the skin would seem to suggest that true carcinoma, in whichever situation, is the result of a disturbance of the normal balance of growth between epithelial and adjacent tissues as the result of previous damage, and there seems to be no need to invoke the aid of embryonic cell-rests or of microbic invasion.

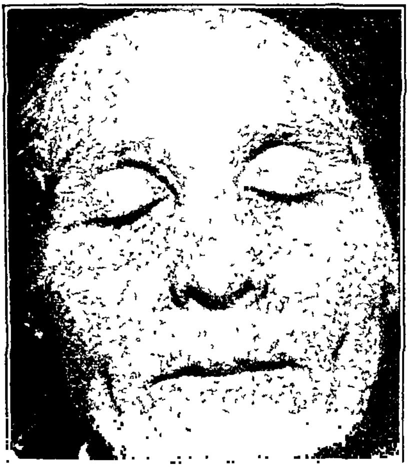
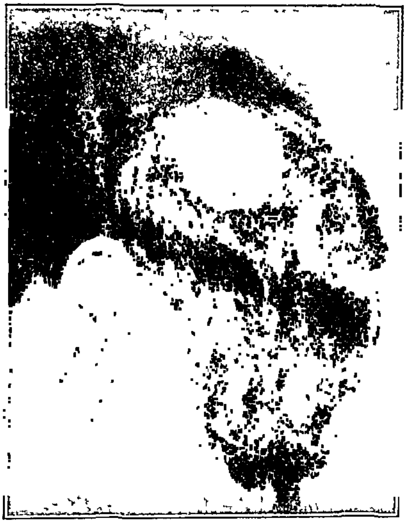
FIG. 1.



Case 1. Epithelioma adenoides cysticum. Reproduction of photograph showing numerous raised rounded tumours situated especially round the eyelids, at the sides of the nose, on the temples, and about the ears

Although it destroys subjacent tissues, it does not invade the lymphatic spaces. Corresponding with the absence of lymphatic invasion, gland infection, and metastases there is an absence of the general disturbance of the health—of the cachexia—which accompanies true carcinoma.

FIG 2.



Case 2 From photograph showing the two largest tumours on the scalp These will be recognised as the growths

FIG 3

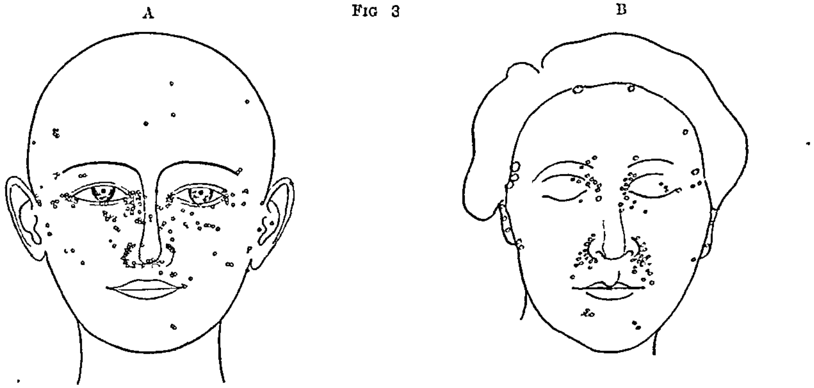


Diagram illustrating sites of origin of 220 cases of rodent ulcer (basal-celled carcinoma) on the face (Dr J. H. Sequeira)

Diagram showing the distribution of the tumours in a case of epithelioma adenoides cysticum (Case 1).

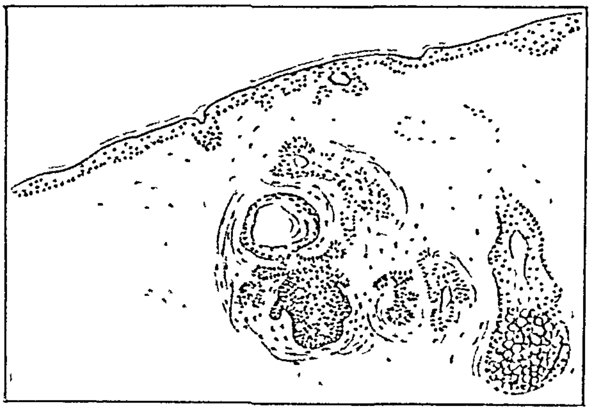
In rodent ulcer, on the contrary, the growths arise, not in areas which have been the site of previous damage, but in regions where benign growths of similar structure and admittedly nævoid nature are known to occur. Rodent ulcer, moreover, does not occur on mucous membranes.

In THE LANCET of Oct. 17th, 1908, I published an account of two cases of multiple rodent ulcer, and drew attention to the close resemblance between the histological features of multiple rodent ulcer and the benign nævoid growths known as epithelioma adenoides cysticum of Brooke. Both these affections are epithelial growths derived from those cells of the basal layer of the epidermis which are normally destined to become pilo-sebaceous follicles; in one word, both are tricho-epitheliomata. They differ mainly in that the rodent ulcer tumours appear late in life and tend to ulcerate, while the benign form appears in childhood and does not ulcerate. They have the same distribution, and before ulceration of the rodent tumours the same clinical appearance. That these affections were in some way related was not a new view, and Jarisch had already suggested the name "tricho-epithelioma papulosum multiplex" for Brooke's disease, and "tricho-epithelioma papulosum rodens" for multiple rodent ulcer.

At the time of writing the paper referred to I had had no opportunity of studying any example of Brooke's affections at first hand, but the following cases have recently come under my care, and they fully confirm the opinion I then expressed as to the close resemblance of rodent ulcer to the "benign" tumours.

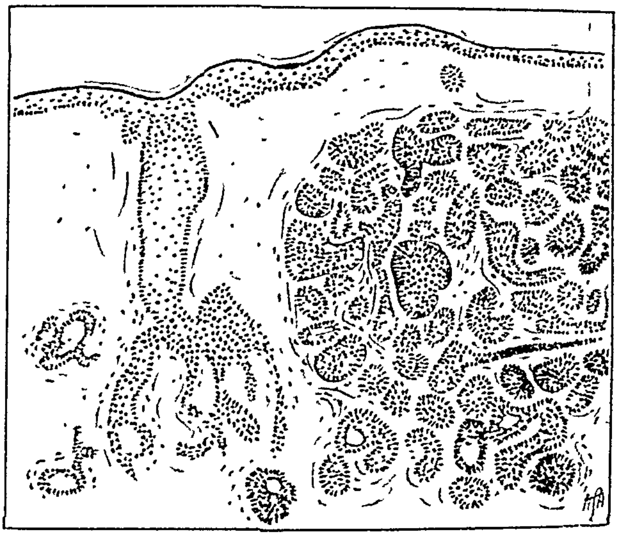
Four cases of epithelioma adenoides cysticum in one family.—These cases show the resemblance to rodent ulcer in appearance, distribution, and pathological anatomy of the growths.

FIG. 4.



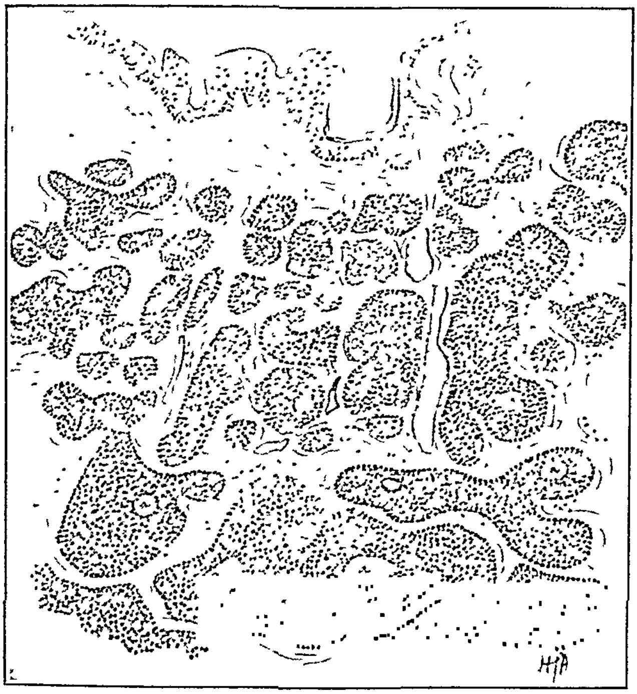
Section at the margin of a tumour from the forehead of Case 1, showing early tricho epithelioma and a small sebaceous gland. (In Figs. 4, 5, and 8 the sections were kindly prepared by Mr. R. G. Canti.)

FIG. 5.



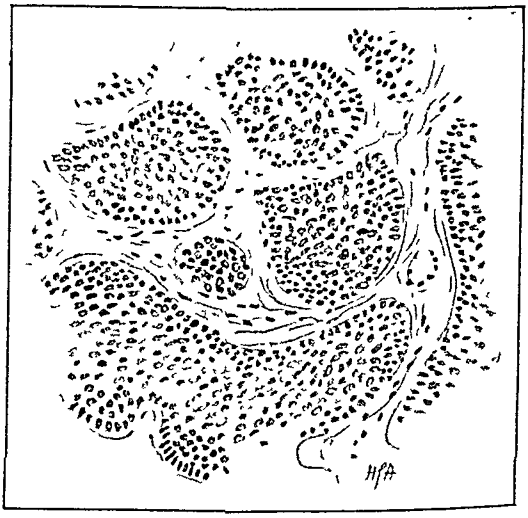
Section from a small tumour from the face of Case 1, showing lobulated growth resembling rodent ulcer.

FIG. 6.



Section from a large tumour of the scalp from Case 2, showing lobulated growth resembling rodent ulcer; at *a*, *a*, *a*, *a* are "cysts." (In Figs. 6 and 7 the sections were kindly prepared by Mr. K. J. A. Davis.)

FIG. 7.

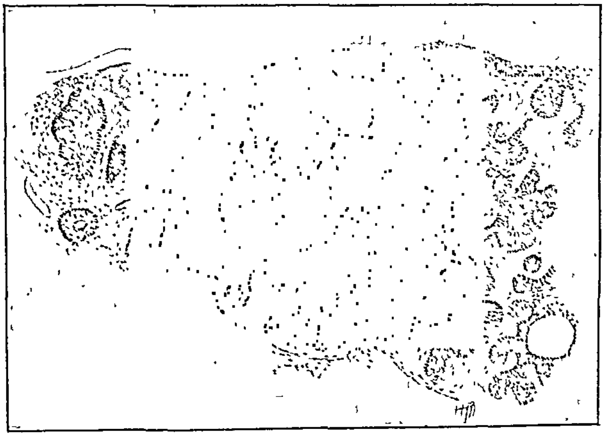


Section (high-power) from large tumour in Case 2, showing lobules made up of oval cells with large nucleus and little or no visible protoplasm. The section shows also the hyaline bodies described by Dubreuilh in sections from a similar case of benign epithelioma of the scalp.

CASE 1.—Housewife, aged 45 years. The eruption was first noticed at the age of 35–37 years. This is not in accordance with the rule that these benign growths appear in late childhood or at about puberty. But they may have been small and unnoticed by the patient, as in the case of her daughter which will be presently mentioned. They increased gradually and more noticeably after confinements. The "eruption" consists of raised rounded nodules, varying in size from that of a pin's head up to nodules half an inch across. They are situated (Fig. 1) in groups: (1) in the naso-labial furrow; (2) at the inner side of the orbit; (3) on the temples; and there are scattered nodules on the forehead and cheeks, on the sides of the neck and behind the ear, on the scalp, and on the shoulders. The nodules are raised, firm, hemispherical, almost waxy in appearance, of the colour of the skin, or, in the case of the larger nodules, dusky red. Minute vessels are coursing over the larger nodules. They all have much the appearance of the rolled edge of a rodent ulcer, but none are ulcerated or crusted, and there are no scars. The nodules on the temples, at the inner orbits, and in the naso-labial furrows are small, from pin-head to split-pea size, and closely packed.

CASE 2.—A son of the previous patient, aged 21 years, presents similar nodules on the face in the same situations and also several much larger spherical nodules on the scalp. The latter are as large as walnuts and prevent him putting on his hat, except at an acute angle. (Fig. 2.) Nothing was noticed on his face until two years ago, but the largest nodule appeared on the head three years ago, and rapidly increased to its present size. The nodules on the scalp are free from hair. There is also a nodule on the chest below the right clavicle, raised, flat, red, and as large as half a marble. The largest nodule on the scalp was removed and examined microscopically.

FIG. 8.



Section of growth from lower eyelid (Case 5) which had been present since childhood. It is obviously a basal-cell epithelioma of rodent ulcer type. It was associated with a typical rodent ulcer of the naso-labial fold, which had appeared in middle life

Incidentally it may be remarked that this case is an example of the so-called endothelioma of the scalp of Spiegler and Mulert, which Dubreuilh and Auché have shown to be a benign epithelioma derived from the basal-cell layer of the epidermis, and to resemble histologically rodent ulcer.[3] The association of the multiple tumours of the scalp in this case with epithelioma adenoides cysticum is interesting and helps to place these tumours in their true position as tricho-epitheliomata, as suggested by their histology. Friebos has recently published a similar case of multiple benign tumours of the scalp associated with multiple tumours of the face, trunk, and limbs. He regards the face and body tumours as tricho-epithelioma (epithelioma adenoides cysticum), but thinks the scalp tumours are of sweat-gland origin. The present writer agrees with Dubreuilh that, although the microscopical appearances of the scalp tumours somewhat suggest a sweat-gland origin, it can be demonstrated that they are really tricho-epitheliomata.

CASE 3.—Another son has recently developed nodules on the scalp, but at present none on the face.

CASE 4.—Another member of this family, a girl, aged 10, has one pin-sized nodule in the left naso-labial furrow, and one on the forehead. These are raised and have a pearly look. With a lens several smaller nodules can be seen on the cheeks and the sides of the nose.

The mother of this family states that she has eight children living, and three of these are affected thus:—*Unaffected*: girl, aged 4 years; four boys, 7, 9, 14, and 16 years; girl, 11 years, a few; two boys, 19 and 21, both affected. The mother's mother and one of her own aunts were also subjects of the disease. It is noteworthy that in most of the published cases mother and daughter have been affected, and seldom the male side.

It is interesting to compare the distribution of the lesions in the case of the mother and of the son with a diagrammatic record of the distribution of 220 cases of rodent ulcer which has been kept by Dr. J. H. Sequeira, and which was published in the Transactions of the Royal Society of Medicine for 1913. It will be readily seen how strikingly they agree. (Fig. 3.)

But it is not only in their appearance and in their distribution that these tumours resemble rodent ulcer; their histological characters are closely similar, so that a section of one of these growths might be pardonably mistaken for one of rodent ulcer. The accompanying drawings from sections of growths in these two cases show that they are made up of oval cells derived from the epidermis. (Figs. 4, 5, 6, and 7.) In the case of one section (from Case 1) there is a strong suggestion of origin from the pilo-sebaceous follicle. (Fig. 4.) These cells, which so closely resemble the cells of rodent ulcer, are arranged in lobules with a marginal palisade layer, and cystic formations similar to those seen in rodents are present here and there. There is no ulceration, and the plasma-cell infiltration is replaced by a fibrous tissue barrier, but otherwise the resemblance is striking.

Before the completion of the study of these cases another patient came under my observation with a condition which seems to show in a still more conclusive manner the relationship between rodent ulcer and benign tricho-epithelioma.

CASE 5.—*Non-ulcerated tumour of the lower eyelid (tricho-epithelioma) present since birth, associated with rodent ulcer of the nasolabial-fold which appeared in middle age.*—The patient, a male aged 37, had two growths, one on the left lower eyelid and one on the left naso-labial furrow. The growth in the lower eyelid was a raised, flat, oval, disc-like nodules ¼ inch in its longer diameter, firm, semi-translucent, and rather redder than the normal skin. It was not ulcerated or crusted. It had been present since childhood—as long as the patient could remember. The growth at the side of the nose was somewhat larger, ulcerated, and with the raised quantity and the other, possibly his own brother, a plus quantity. I may be told that it is a question of their respective constitutions. No doubt it is, but that again is meaningless unless we are prepared to explain what constitutes a constitution.

---

[3] Epithéliomes Bénins Multiples du Cuir Chevelu—Dubreuilh and Auché, Annales de Dermatologie et de Syphiligraphie, 1902, p. 545.

Well, I am going to be bold enough to venture upon such an explanation. The constitution of any given person depends upon the accuracy of his metabolic changes. By accuracy I mean the proper coordination of his intake, his assimilation, and his output. If at the outset he is well endowed with coördinative power, if, as the French say, he is originally well "equilibriumed," then his constitution is good. If, however, there be a piece which does not quite fit the dovetail, whether it be too large or too small, a thought too narrow, or a trace too wide, the other members are strained; and though in favouring conditions the machine may appear to work smoothly enough, the weakness becomes painfully apparent in times of stress. Of these three, intake, assimilation, and output, in the early years, when the constitution is being stereotyped as it were, the assimilation is by far the most important. In later life the importance of this element wanes, and it is the output which becomes paramount. Adequate anabolism in infancy and childhood, energetic katabolism in adult life and advancing years, such are the bulwarks of the constitution.

Time was, and not so very long ago, when our knowledge of matters metabolic was very rudimentary. Tissue change was regarded partly as a nervous phenomenon, but mainly as a dietetic drama, in which a harmless enough creature called uric acid very successfully posed as the villain. To-day we know more, but there is much knowledge still to seek. We know that metabolism is under the direct control of the internal secretory glands. We know that these glands preside over growth and development in infancy and childhood, that they are essential to mental, physical, and reproductive efficiency in adult life, and that they are responsible for the maintenance of katabolic balance in the period of decline. It is therefore no exaggeration to define the constitution of an individual as the resultant of his internal secretions. The greater includes the less, and if this be true of the body as a whole it is conspicuously so of the blood-vessels. The internal secretions, the hormones, are poured straight into the vital fluid which traverses the arteries, nourishing and, peradventure, irritating them in its passage. The quality of this fluid, its constitution, must depend to an incalculable extent upon the tribute which it receives from the ductless glands. And this dependence is not only direct but indirect; for if, owing to a faulty gland, the general metabolism be faulty, the stream contains elements which it ought not to contain, and the conduits become injured thereby.

This, then, is the answer to my self-imposed question as to how it is that in some people the arteries readily degenerate, and in others similarly circumstanced they do so reluctantly, if at all. If the equilibrium of the glands is good, the metabolism is good, the powers of resistance are good, and toxins are brought to naught. The toxins may gather in numbers innumerable to hurl themselves with frantic fervour against the walls of the citadel, but they will do so in vain so long as the glandular defenders work in unison. If the equilibrium of the glands be impaired the metabolism is impaired, the combative power is lowered, and microbes flourish exceedingly; the blood is no longer antiseptic; it has become a circulating bouillon or a stagnating agar-agar in which bacillus and coccus and spirochæte gambol together in the impious harmony of a multiple infection.

This question of the metabolic importance of the ductless glands has a further and a very special application to the question of at any rate two of the recognised forms of arterial degeneration—namely, those which are characterised by a deposit of lime salts. Four of the ductless glands, the ovary, the adrenal, the thymus and the thyroid, are very actively engaged in the metabolism of calcium. It has long been known that osteomalacia was curable by removing the ovaries, showing that the ovaries are vigorously engaged in the excretion of the calcium salts. It now appears that a means equally effective, though less dramatic, of controlling this loss is open to us by the exhibition of suprarenal extract. This shows that the suprarenals cause retention of the calcium salts, and normally antagonise the ovarian activity in this direction. It is believed on good evidence that the main excuse for the existence of the thymus is that it causes retention of the calcium salts while the bony skeleton is being developed. The part played by the thyroid in this matter is rather enigmatic. In the first place there is the well-known fact that a great loss of calcium occurs in Graves's disease; in the second, there is ample evidence to show that the thyroid plays a most important part in fixing the calcium salts in the body during the growing period; and thirdly, there is the fact of the depressed calcium metabolism which is conspicuous not only in myxœdema but in old age. Blair Bell suggests that the calcium salts are differently employed by the organism at three different periods of life. He says: "Until puberty calcium is chiefly employed in building up the skeleton; after this it is used for reproduction; and lastly (and pathologically if the termination of life be pathological), for producing the changes which are associated with senility—namely, the retention of lime salts in the tissues, especially in the arteries." This is an ingenious theory with which in the main I am inclined to agree, though I cannot subscribe to the suggestion that we are meant gradually to be transformed into pillars of chalk, to make our exit crumbling, and grittily to greet the resurrection. That many of us may do so there is, alas, no doubt, but if we are to believe Metchnikoff and his Bulgarian bacilli it is evident that we shall do so through some metabolic fault of our own, and not because the Fates have willed it. The responsibility for that fault I believe to rest with the thyroid gland; not, perhaps, directly, but more probably indirectly, in its capacity of the master gland of the endocrinous system.

For we have to remember that as yet we know very little about the interaction of these internal secretory glands. It is surmised, in all probability correctly, that certain of these glands antagonise certain others, and that some of them reinforce others. Thus when in a given case we administer, say, thyroid extract with success, we cannot be certain that it was thyroid essence that was lacking; it may have been some other gland that was lazy, and our remedy has stimulated it to a resumption of its duties. For the present, however, we are obliged to speak empirically, and assume that if thyroid extract produces the desired result it was inadequacy of the thyroid gland which caused the symptoms. In the present state of our knowledge this practice is pardonable, and even necessary, but it is right that we should from time to time remind ourselves that the practice is but a makeshift. And [illegible] he thyroid than to [illegible] because this gland [illegible] which the *others* revolve. It is the master-key which locks one door and unlocks another, according to the necessities of the moment. That is one of the reasons for its *being so easily exhausted.* The ovaries seem to give it much more trouble than the testicles, for thyroid insufficiency is quite three times as common in woman as it is in man. This may be due to the fact that the testicle appears to be far less active in excreting calcium than the ovary.

That the thyroid presides over, and in a large measure directs, the metabolism of the calcium salts there can be no doubt, but whether it interferes directly through its own secretion, or whether indirectly through the agency of some other gland or glands, it is impossible at present to say. It has been abundantly proved, and anyone may satisfy himself of the fact in any case of rickets, that the thyroid gland is instrumental in fixing the calcium salts in the growing organism. It has not been proved, but I am convinced it is true, that in the case of the adult and declining organism the aid of the thyroid can be invoked to secure the excretion of these salts. I have seen hard and uncompromising tophi completely disappear under the influence of thyroid extract, and I have even persuaded myself that a cord-like radial artery has become more malleable under the same gentle persuasion. By this, however, I must not be understood to be suggesting that calcified arteries can be regenerated or rejuvenated by thyroid extract. Nor am I of those curiously unimaginative people who would seek to rid an aorta of its plaster by exhibiting drugs which in a test-tube can be made to dissolve the salts of lime. When arteries have degenerated their course is run. Even if we could, which we cannot, relieve them of the whole of their burden of lime, it is quite certain that we should do harm rather than good, for a certain amount of calcium in the walls of a worn-out artery is just as surely a preservative element as the calcium in an extinct pulmonary tubercle. The deposit of lime is merely the brand of the degenerative process. It is not the process itself. If there were no calcium wherewith to patch the arterial walls the end would only come more quickly. The degeneration is there; the calcium is only the splint which supports the cripple, without which he would the sooner be undone. The part played by the thyroid would thus seem to be that of a regulator of calcium metabolism. It may promote the retention of the lime salts when these are insufficient, or it may ordain their expulsion when they are present in excess. In order to do this, however, the thyroid must be an effective generalissimo. He may be somnolent, but he must, when roused, be capable of effective interference. Unfortunately, with advancing years this is precisely what he is not. Whether from mere weight of years or from exhaustion in fighting toxins he becomes senile and fails to maintain discipline, with the result that calcium which ought to be excreted is retained and the amount necessary to the preservation of the arterial wall is augmented to the point where the wall is composed mainly, if not entirely, of calcareous matter. Lime has ceased to be a servant; it has become a master. Freed from the control of the exhausted thyroid it becomes a parasite. One day the mortar cracks and breaks, and the tenement falls.

This, then, is what I venture to offer for your consideration. If we would understand the real causes of arterial degeneration we must look deeper than the banal surface causes, such as gout and syphilis, which are not always operative, to the limestone formation which lies beneath. Here we come upon the powers of resistance of the individual, which rest upon his metabolic efficiency. This in its turn is supported and maintained by the vigour and harmony of his ductless glands. When the vigour and harmony of these glands is impaired, by circumstances which may be congenital or acquired, the metabolic efficiency deteriorates and the powers of resistance decline. Toxins now succeed where before they were defeated, and degenerative processes become operative. In the degenerative processes which attack the vascular system the fibrosis and the calcareous deposit are originally conservative measures which proceed to dangerous excess only because of the want of control of the endocrinous glandular system in general, and of its master gland, the thyroid, in particular. Thus in the presence of vascular degeneration we are powerless. When we are appealed to early enough we may do something to defer its arrival, and the degree of that something will depend upon our working knowledge of the physiology and clinical behaviour of the ductless glands. If we can learn to stimulate the efficiency and promote the harmony of these potent metabolisers we may do much. Without such knowledge we are impotent.

But, sooner or later, by one means or another, whether by calcium or fibrosis, or what not, the end must come. Even though a man should live by bread alone, eschew wine, laughter and song, live laborious days and suffer loveless nights, he cannot escape. The moving finger writes, the dreaded spectre waits, and the mourners go about the streets. Such is the conclusion of all degenerations, and the conclusion, most conspicuously, of arterial degeneration. And it brings the conclusion of my contribution—a contribution which has proved nothing, disproved nothing, and suggested little, on a subject of absorbing interest and abiding importance. It reminds me of Omar Khayyám:—

> Myself when young did eagerly frequent
> Doctor and saint and heard great argument
> About it and about, but evermore came out
> By that same door wherein I went.
>
> With them the seeds of wisdom did I sow,
> And with mine own hand laboured it to grow,
> And this was all the harvest that I reaped—
> "You came like water, and like chalk you go."

ETIOLOGY OF ENDEMIC CRETINISM, CONGENITAL GOITRE, AND CONGENITAL PARATHYROID DISEASE:

ABSTRACT OF EXPERIMENTAL RESEARCHES.[1]

BY ROBERT MCCARRISON, M.D. R.U.I., M.R.C.P. LOND.,
MAJOR, INDIAN MEDICAL SERVICE, ON DEPUTATION IN CONNEXION WITH THE STUDY OF GOITRE AND CRETINISM IN INDIA.

MY previous researches[2] have led me to believe that the exciting agent or agents of goitre exist in the intestinal tract of sufferers. In the course of experiments, having for their object the identification of such an agent or agents, I have had occasion to feed white rats (1) on the filtrate of an emulsion of goitrous persons' fæces, and (2) on aerobic and on anaerobic cultures of organisms grown from the fæces of goitrous persons. A number of rats were also confined in dirty, unhygienic cages, which were grossly contaminated by their own alvine discharges, with a view to determining the influence of such conditions of life on the development of goitre.

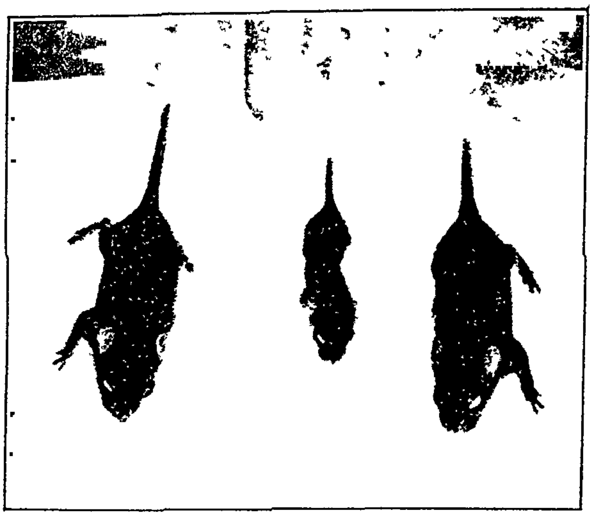
---

[1] [illegible] ary number.

[2] [illegible] London, B., [illegible] ; 1911-12, B. vol. lxxxiv., pp. 155-56; THE LANCET, 1913, vol. i., pp. 147, 219, 365.

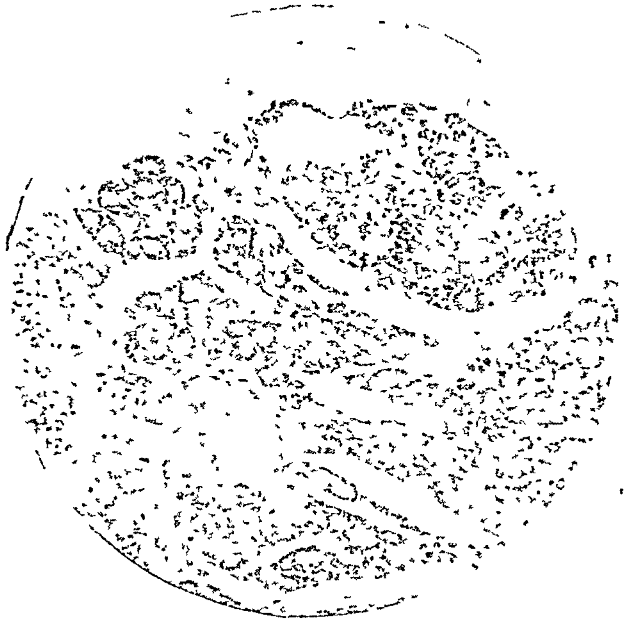
Among the animals treated in these ways were a number of adult females which developed goitre of greater or lesser degrees of intensity. These gave birth during the period of the experiment—March 15th, 1913, to Sept. 15th, 1913—to 146 young. The fathers of these animals were also sufferers from experimentally produced goitre. Of the young rats 63 were removed from the cages for examination. The thyroids of all except 7 were examined one to four days after birth. Of these offspring of goitrous parents 3 were cretins—viz., 4·75 per cent.; 40 had congenital goitre—viz., 63·5 per cent.; 15, out of 47 in which the parathyroids were found, had congenital parathyroid disease—viz., 31·9 per cent.; and 21 were normal—viz., 33·3 per cent.

FIG. 1.



Litter of three young rats, aged 20 days, the offspring of a mother which consumed fæcal filtrate prior to and during pregnancy. The animal in the centre is a cretin.

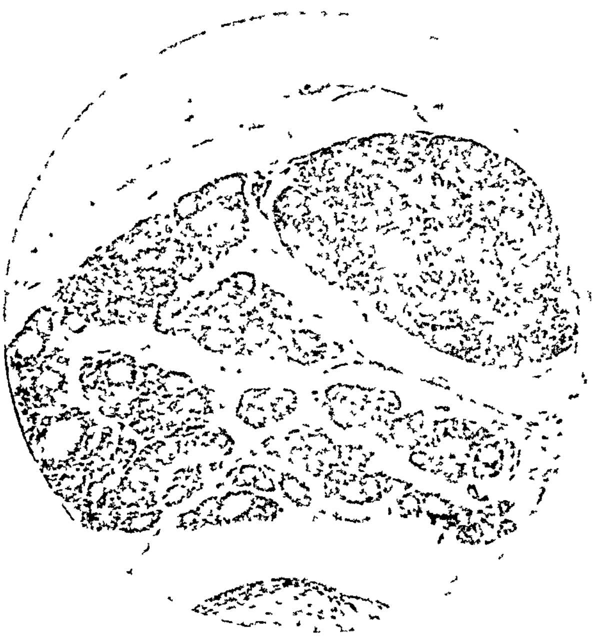
FIG. 3.



Thyroid and parathyroid glands of a 4 day old rat, showing an area of disease in the thyroid and extensive destruction of the parathyroid gland by hæmorrhage into its substance Magnified 180 diameters

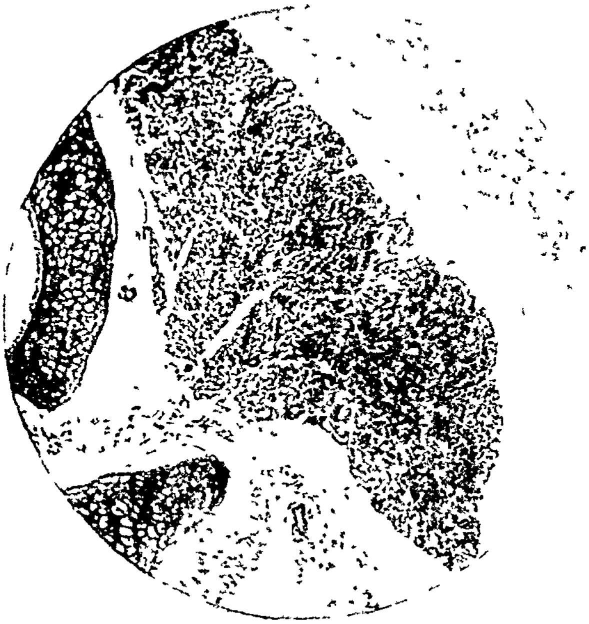
Details of results.—Of 5 animals born in the filthy, unhygienic cages all showed signs of thyroid hyperplasia. The parathyroids were found in all 5 cases, and were not affected by the goitrigenous influences.

FIG. 2.



Normal thyroid and parathyroid glands of a 4 day old rat Magnified 180 diameters

FIG. 4.



Thyroid and parathyroid gland of a 4 day old cretin rat, showing almost complete fibrosis The arrow indicates the situation of the parathyroid gland. Magnified 90 diameters

Of 16 animals, born of a mother which consumed the filtrate of an emulsion of goitrous fæces prior to and during pregnancy, 3 were cretins (Fig. 1), 7 had thyroid hyperplasia—in 2 of these there was also partial fibrosis of the thyroid, and 7 were normal; while 5, or 38 per cent., had congenital parathyroid disease. The thyro-parathyroid apparatus of only one cretin was examined microscopically, as the mother ate the other two. The clinical features of all three were similar (Fig. 1)—namely, stunted growth, curvature of the spine, low weight, and defective powers of motion. The thyroid and parathyroid glands of the cretin which was examined were completely destroyed, the parenchyma cells being almost wholly replaced by fibroblasts (Fig. 4). There is little doubt, therefore, but that the thyro-parathyroid apparatus of the other two cases were similarly affected.

Of 17 animals, born of mothers which consumed aerobic cultures on agar of fæcal micro-organisms, 7 had normal and 10 had markedly hyperplastic thyroid glands. The 10 animals having disease of the thyroid were born of two mothers which consumed fæcal aerobes prior to *and during* pregnancy. The 7 animals having normal thyroids were born of one of these mothers which consumed fæcal aerobes prior to *but not during* pregnancy. The noxious action of the bacterial cultures was thus demonstrated. The parathyroids were found in 11 out of the 17 cases and were normal in all.

Of 25 animals, born of mothers which consumed fæcal anaerobes, 8 had normal or almost normal thyroids, while in 17 the thyroid gland was markedly hyperplastic. The parathyroids were diseased in 10 out of 18 cases in which they were seen, or 55·5 per cent. The parathyroid disease consisted in marked congestion, hæmorrhages into the gland which destroy large portions of its substance, and in fibrotic changes (Figs. 2 and 3).

Three important facts are to be noted in connexion with these results: 1. That out of 16 animals, born of a goitrous mother which consumed fæcal filtrate prior to and during pregnancy, 3 were born cretins, while the 47 animals born in other cages showed no clinical or pathological signs of this condition. 2. That of 31 animals, born of goitrous mothers which consumed either fæcal anaerobes or the filtrate of a fæcal emulsion, 15 were found to have congenital parathyroid disease. Of these, two-thirds were born of mothers consuming the anaerobic cultures, while one-third were born of a mother consuming a fæcal filtrate which contained the toxic products of these anaerobes. The parathyroids were normal in 16 animals born of goitrous mothers in other cages. 3. Fæcal organisms which grow aerobically on agar, while capable of causing marked hyperplasia of the thyroid gland, do not appear to be capable of producing any ill-effect on the parathyroid glands.

Conclusions.—1. Of the offspring of goitrous parents a small percentage are born cretins, approximately 63 per cent. are born with congenital goitre, 32 per cent. are born with congenital parathyroid disease, and 33 per cent. are born with normal thyroid and parathyroid glands. 2. Cretinism and congenital goitre are due to the action of toxic substances derived from the intestines of the goitrous mother on the fœtal thyro-parathyroid mechanism. Cretinism represents the maximum, and comparatively rare, effect of these toxins; congenital goitre their minimum, and comparatively common, effect. Between these extremes all degrees of thyroid involvement may occur with or without associated swelling of the gland.[3] 3. Congenital parathyroid disease is due to the action on the fœtal gland of the toxic products of organisms, present in the intestine of the goitrous mother, which are capable of growth under anaerobic conditions.[3]

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF QUININE POISONING.

BY LEONARD MYER, F.R.C.S. EDIN.

THIS is a brief account of a case of acute poisoning by quinine with a few remarks thereon. It is the more interesting because so recently as Jan. 17th and Jan. 24th there were reports of poisoning by this drug in THE LANCET and also because my patient was intelligent and able to give some definite story of the subjective symptoms after her recovery.

The patient, aged 20, was three days late with her menstrual period. She procured some quinine sulphate from two chemists, which I have ascertained amounted to 2 drachms; she partly dissolved this in lemon juice and water and drank the mixture at 2.30 P.M. A quarter of an hour after she felt "dizzy as if she were drunk." By 3 P.M. she could hear her friends talking, but could not make out what was said and soon after she was quite unconscious. At 5.30 I reached her after an urgent call. I found her comatose, her pulse was 120 and feeble, her respirations were shallow, occasionally sighing and 20 per minute. Her temperature was 98·6° F. She took no notice even when shouted at. There were obvious signs of vomiting, which had included some undissolved quinine; she was lying on her bed fully dressed. Her pupils were widely dilated. Some hot coffee was quickly prepared, but a rectal injection was prevented by the fact that the bowels had been very freely evacuated under her, likewise her bladder, and I was without adequate assistance. I therefore administered 6 minims of liquor strychninæ hypodermically and a quarter of an hour later when I shouted at her she said, "I cannot see and I don't know what you are saying." Her pulse was then much stronger and I left her with instructions to the husband to call me if he was anxious and that in any case I would come again later. I saw her again at 10.30 P.M. She was sleeping and very drowsy. I roused her by shouting. Her pupils were still widely dilated. She was unable to perceive a very strong incandescent gas light in the room, she also complained of "buzzing" in her ears. I afterwards learnt that about this time she felt "flashes of light and sound," that her feet felt cold and that they wanted to move but could not do so. The coldness spread upwards and before it reached her arms, she could move her legs. Eventually, about 6 A.M. the next day, she "could feel the parts getting well," and on being asked by her husband if she could see she stared at the strong light for five minutes before she was able to make anything out and the first thing was the clock by the bedside which "only gradually took shape." It was 24 hours more before she could see well and before the buzzing ceased. She is quite well now, and needless to say her period has not appeared.

---

[3] Proceedings of the Royal Society of Medicine (Medical Section), 1908, vol. ii., pp. 1-31; THE LANCET, Oct. 31st, 1908, p. 1275.

The books describe the result of a big dose of quinine and also of chronic poisoning "cinchonism." The only description of a case like mine was of the Orientals in THE LANCET of Jan. 17th (p. 174), and there the subjective symptoms are not related. Nor is any antidote stated or recommended in the books. Had I been called earlier—i.e., before coma had set in and before vomiting had taken place—the treatment would have been 30 grains of ammonium carbonate in water to precipitate the unabsorbed quinine, as an emetic and alternatively as a stimulant. Failing vomiting by this means the stomach tube and bicarbonate of soda would be indicated. In this case vomiting had occurred and it was reasonable to suppose that in the three hours which had elapsed the remainder of the "poison" had been absorbed.

The quinine was taken under the false impression that it was an emmenagogue and in the cases referred to it was taken in large doses by accident.

A CASE OF APPENDICITIS WITH SEVERAL POINTS OF INTEREST.

BY H. F. G. NOYES, M.B., B.C.CANTAB., M.R.C.S.ENG., L.R.C.P. LOND.

ON Jan. 2nd, in answer to a wire, I met at Worthing station the patient, a man, aged 32, on a visit to England from Australia. The history of his illness is as follows. At an afternoon pantomime performance on Dec. 31st he was seized with violent abdominal pain, which necessitated his leaving the theatre and taking a cab to a hotel. He was seen soon after by a medical man, who gave him a hypodermic injection of morphia. His temperature was 101·4° F., and pulse 104. Later in the evening he vomited. On the next day his temperature had dropped to normal and his pulse was 76. An ounce of castor oil was given, and his bowels were moved several times. The medical attendant was not satisfied with the patient's condition, and on the morning of Jan. 2nd called a surgeon in consultation. An acute perforated appendix was diagnosed and immediate operation was ordered. This the patient refused, and insisted on travelling by the first train to Worthing. A nurse was sent with him to administer brandy should the pulse become weak on the journey.

On arrival in Worthing the patient was very collapsed. The pulse was 120 and thready in character. He was conveyed to a nursing home and consented to an immediate operation. The abdomen was as "hard as a board" and acutely tender, especially in the right iliac fossa and hypogastrium. After opening the abdomen the appendix was found to run downwards into the pelvis. It was 6½ inches in length, there was a kink about 1 inch from the cæcum, and the distal end was bulbous, gangrenous, and perforated, the aperture being about the diameter of a lead pencil. The tissues were in a very friable condition, and merely the bare removal of the appendix was attempted. The cavity where the appendix lay was swabbed out, and a large soft drainage-tube left in running down into the pelvis.

The patient stood the operation remarkably well, and as soon as he had come round from the anæsthetic was placed in Fowler's position. During the next three days—i.e., Jan. 3rd, 4th, and 5th—the patient vomited small quantities of bile, and in response to calomel by mouth and turpentine enemata passed a fair quantity of flatus. The pulse varied between 70 and 90, and was fairly full in character. The abdomen became gradually more and more distended in the epigastrium and hypochondria, the liver dulness was displaced upwards, and the "coin-sound" was elicited over an area which corresponded to an enormously dilated stomach. On the fourth day after operation considerably over a quart of fæcal-smelling vomit was brought up. The patient was very collapsed afterwards, and his pulse became thready and about 130, but later in the evening he felt better and was less distended. This fæcal vomiting occurred twice every 24 hours, and continued for eight days. After the vomiting the patient always felt relieved, and the epigastric distension became temporarily less. Meanwhile nourishment was administered by means of nutrient enemata.

I met Mr. W. H. Battle in consultation on Jan. 4th and 9th, and am much indebted to him for valuable advice on the case. He recommended lavage of the stomach. This I did once, but the patient was very collapsed afterwards, and asked that he should be allowed to wash out his own stomach by the natural method of vomiting. He was provided twice daily with a quart of normal saline; this he drank at one draught and ejected immediately afterwards mixed with the fæcal contents of his stomach. By this means the vomit became gradually less offensive and smaller in quantity, until Jan. 14th, when he was unable to return the saline. From this day his condition rapidly improved and he began to take food by the mouth. The abdominal distension quickly disappeared and his recovery was uneventful except for a superficial stitch abscess in the abdominal incision.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Gastro-jejunostomy.

A MEETING of this section was held on March 10th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. HERBERT J. PATERSON read a paper on Gastro-jejunostomy and the Principles which should Determine its Application. He said that during the past 15 years there had been a great improvement in the results of gastro-jejunostomy, both immediate and remote. This improvement had been attributed largely to the adoption of the "short-loop" operation. He suggested the possibility that this improvement was due, not to the particular method employed, but to a general advance in surgical technique. He pointed out that a gastro-jejunostomy opening should be as near to the pylorus as possible. This was anatomically impossible in the posterior "short-loop" operation. Therefore, the posterior "short-loop" operation was unsound physiologically, but anatomically good; the anterior operation was good physiologically, but anatomically bad. He was inclined to think that on the whole the remote results of the anterior operation were rather better than the remote results of the posterior operation. Mr. Paterson pointed out some of the mechanical defects which might prevent the patient gaining complete relief, but insisted that the chief cause of failure after gastro-jejunostomy was its performance without proper indication. He gave in detail the reasons for the views which he had been advocating for years, that gastro-jejunostomy was a physiological and not a drainage operation. It was difficult by any mechanical explanation to explain the beneficial effects of gastro-jejunostomy. How then did it act? He stated that the presence of bile and pancreatic juice in the gastric contents was a constant feature after gastro-jejunostomy. The proof of this was the constant increase in mineral chlorides in the gastric contents after gastro-jejunostomy. This increase was not due to increased activity of the gastric secretion, and so must be due to chlorides added from without—i.e., through the anastomosis, because (1) the total chlorides of the gastric contents were diminished; (2) undoing a gastro-jejunostomy diminished once more the amount of mineral chlorides; (3) if an entero-anastomosis was performed the increase in the mineral chlorides did not occur; (4) in cases in which there was marked excess of bile in the gastric contents there was a marked excess of mineral chlorides; and (5) as a rule the increase in mineral chlorides did not follow operations other than gastro-jejunostomy. Mr. Paterson concluded that the average amount of bile which regurgitated into the stomach was between 5 and 10 per cent. He discussed the effect of the different types of operation in the regurgitation of bile, and concluded that the type of operation performed was of less importance than the manner in which it was performed. The reasons for the beneficial effects of gastro-jejunostomy and the indications for its performance were discussed, and in conclusion the following four practical conclusions were stated: 1. That the type of gastro-jejunostomy employed was of less importance than the manner in which it was performed. 2. That occlusion of the pylorus was an unnecessary complication of gastro-jejunostomy and was based on erroneous pathology. 3. That if gastro-jejunostomy was a physiological operation, its use for the treatment of gastric hæmorrhage was correct and explicable. 4. That if gastro-jejunostomy was a physiological operation, then it was as efficient a treatment for ulcers of the body of the stomach as for ulcers near the pylorus; in other words, gastro-jejunostomy was preferable to excision.

Sir FREDERIC EVE thought that all surgeons would agree that gastro-enterostomy was a physiological operation, and said that he had been in the habit of teaching that the good results which followed it were due to the regurgitation of bile and its neutralisation of the gastric contents. He agreed almost entirely with Mr. Paterson's main conclusions. The stoma should be placed near the pylorus. He had found that cases of duodenal ulcer did as well without as with occlusion of the pylorus. He agreed that excellent results followed gastro-enterostomy for an ulcer in the body of the stomach, and also that excision of the ulcer was unnecessary. Cancerous transformation of the simple ulcer was exceedingly rare.

Dr. A. F. HERTZ said that by the use of X rays he had come to the conclusion that the operation acted almost entirely mechanically. If its effect was merely to render the gastric contents alkaline, could this not be obtained more readily by giving alkalis? A single examination of the contents one hour after a test meal was not sufficient evidence, and should be repeated at frequent intervals. The diminution in the total acidity could be easily explained on the supposition of drainage, as the products of digestion were not retained so long in the stomach, and these products formed the stimulus for the secretion of the gastric juice. He had seen many cases of gastro-enterostomy for gastric ulcer where the patient had not been benefited by it. If the operation was a physiological one, how were its good effects in duodenal ulceration explained, and how were they explained in those cases where entero-anastomosis was performed as well? Gastrostaxis benefited so much by medical means alone and often did so badly after gastro-enterostomy that he thought it was not justifiable for that condition.

Mr. J. F. DOBSON said that 50 per cent. of the cases in which a gastric ulcer had been excised recurred, and recorded two cases in which the recurrence had taken place at the site of the excision and had led to perforation. He thought that the results of excision of an ulcer on the lesser curvature were so bad that the operation should be discontinued. If gastro-enterostomy combined with excision were employed a high mortality was to be expected. The only ulcers suitable for excision were those situated on the anterior wall of the stomach and which were easily accessible.

The PRESIDENT said that the cases in which it could be said most certainly that the operation would be a success were those in which pyloric obstruction was present. This suggested that the mechanical factor was important. He still held that excision of a gastric ulcer was good practice, and his results had been most satisfactory. He thought that during the examination of malignant ulcers one found clear evidence that they were sometimes grafted on simple ulceration. Gastro-enterostomy did not prevent gastric ulcers from forming, and he had experience of cases where fresh ones developed after the operation.

SECTION OF THE HISTORY OF MEDICINE.

Exhibition of Objects of Interest.—Art and Epigram regarding Science and Medicine in Relation to Death.—Healing Wells and Waters, with a Suggestion as to the Origin of the Votive Offering.—Some Physiological Phantasies of Third Century Repute.—A Relic of the King's Evil.

A MEETING of this section was held on March 4th, Sir WILLIAM OSLER, the President, being in the chair.

Dr. Haldin D. Davis and Mr. Harold S. Gettings were elected members.

Mr. WILLIAM BUCKLER and Professor RICHARD CATON exhibited (1) a find of [illegible] Colophon in Asia Minor; and (2 [illegible] d Roman *Surgical Instruments* [illegible] Stewart Milne, of Hartlepool.

Dr. F. PARKES WEBER read a paper upon Art and Epigram regarding Science and Medicine in Relation to Death. He referred to typical epigrams and works of art illustrating the various ways in which the idea of death might be related to medicine and the allied sciences. Many of the objects to which attention was drawn related to sanitation and the past want of hygienic methods, as well as to the prevention of unnecessary death. A considerable portion of the paper dealt with satirical epigrams and poetry, as well as with the caricature in art of the work of physicians and surgeons.

Dr. DAN MCKENZIE read a paper on Healing Wells and Waters, wi [illegible] Origin of the Votive Offering. [illegible] e all other primitive therapeutic [illegible] tation to qualities other than medicinal, although some physical or chemical peculiarity might be the origin of their reputed healing power. Although the classification into mystical, rational, and combined therapeutic methods was the more natural, that into magical, religious, and physical would be used for the sake of convenience. *Magical water cures.*—Magical laving was used for skin and eye diseases, as in the cure of Naaman's leprosy and in many other instances in more modern times. Another variety of this was the transference cure to water. *Religious water cures.*—The term "religious" was used in the [illegible] ism was common in regard to [illegible] was credited with the curing virtues. Well cures of this class were widely distributed in space and time, antedating the rise of the world religions, and continuing into them. Zem-zem, at Mecca, the Asklepian holy wells in Greece and Rome, and the Pool of Bethesda at Jerusalem were instances. The water-spirit was closely associated with the genesis of life in primitive thought. The truth of this statement was evident in the facts that children's diseases, sterility in women, and paralysis were cured at wells, and that there was a large collection of myths and legends having their basis upon some such idea. Probably the idea was linked on to the fact of the life of the fœtus in liquor amnii. "Rag wells" and votive offerings.—A common practice was for the patient to leave a rag of clothing attached to a tree near the well, or to throw a pin into the water. Was this a votive offering? Votive offerings were of two kinds—namely, those suggested by gratitude or with the idea of payment, and those in which no evidence of the gratitude motive could be perceived. Rags and pins at wells were of the latter class, as were representations of diseased parts, &c., left at shrines. This was fundamentally a magical custom, dependent upon the expectation that the deity's protection of the rag, &c., would also extend to the patient during his absence; the custom was an instance of "telepathic" magic and was related to the wearing of charms and amulets. Physical water-cures.—This class contained a small number of more or less rational cures. But first of all, mystical cures were discussed. Of these latter, the most interesting were the shock treatment of disease, especially of insanity and rabies, by water. Among the rational cures might be mentioned the cold and vapour baths practised by the American Indian, by native Australians, and in Russia.

Mr. B. GLANVILL CORNEY read a paper on Some Physiological Phantasies of Third Century Repute. After pointing out that exact anatomical knowledge was a necessary possession before physiological functions could be intelligently studied and discerned, Mr. Corney observed that empirical lore accumulated very slowly, and by chance rather than design. So that centuries might well have elapsed after anatomy began to be practised at Alexandria as a succedaneum to the acquirement of surgical and medical skill before physiology joined hands with it. He therefore claimed justification for describing as phantasies some beliefs in the realm of physiological phenomena enumerated by Pliny, and reiterated in the third century A.D. by Solinus, from whose "excellent and pleasant worke" the "*Polyhistor*, contayning the noble actions of humaine creatures, the secretes and providence of nature," &c., he quoted passages "translated out of Latine into Englishe by Arthur Goldinge, Gent., London, 1587." This book by Solinus was at one time known as "Collectanea Rerum Memorabilium," and was one of the first classics that appeared in print. It was primarily a cosmographical sketch, containing, besides its descriptions of lands and seas, a brief historical outline about the city of Rome, and notices of various peoples, their cults, rites, and customs, together with distinctly marvellous accounts of animals, plants, and minerals. Sentences were copied wholesale from Pliny's Natural History; some also from Pomponius Mela, of whose "De Situ Orbis" Pliny himself made considerable use; and Mr. Corney was inclined to regard Solinus, if he might be judged by this one work which had come down from him, as little more than a literary hack. The passages quoted in the paper bear upon gestation, parturition, and development, and not the least merit of Golding's translation is its extraordinary accuracy in spite of the quaintness of his language and the solemn air of truth with which he invests the most extravagant absurdities. In the remarks read, Solinus touches on the age limit of fecundity, both in man and woman, and cites the cases of Masinissa and Cato, who became fathers when "ful fourscore yeare old." He mentions cases of twins conceived separately, "who béeing carryed both in one burthen, had notwithstanding lyke distaunce of time betwéene their birthes, as there was distaunce betwéene heir begetting"; and refers to some of the signs and sufferings of pregnancy and phases in fœtal development, and the different comportment of the sexes in utero. "It is against nature for the byrthe to come foorth with his féete forward," says Solinus; "and, therefore, as Children hardly borne, they are called in Latine *Agrippa*," and "are for the moste parte unfortunate and short lived." After alluding to "Cornelia the mother of the Gracchuses," as Golding calls them, as an example of imperforate hymen, Solinus adventures the popular interpretation of the name "Cæsar," "because he was the firste of the Romaines that was ript out of his mother's wombe"; and explains that the name "Vopiscus" is applied to the survivor of twins, one of whom has perished through being born prematurely. After alluding to some vagaries of dentition, he observes that Zoroaster was the only man who ever "laughed the same howre he was borne"—which brought him excellent luck—and that Heraclitus and Diogenes the cynic, "did never abate one whittle of theyre stiffe stomackes, but treading under foote the fformes of all casualties, continued unchangeable in one purpose, againste all gréefes and miseries." Quoting one or two more negative peculiarities, such as Antonia's (the wife of Drusis) who "didde never spitte," and Pomponius, the poet who "did never rasp," Solinus goes on to mention prodigies of strength and strange abnormalities of muscular and bony development, concluding with the audacious story about Milo, of Croton, who "with the stroke of his bare fist, felled an Oxe starke dead, and eate him upp himselfe alone the same day that he killed him, without overcharging his stomacke." The first printed edition of the *Polyhistor* emanated from the Jansen press at Venice, in 1473. The latest edition of his text, and undoubtedly the best, is Mommsen's, published in 1864. His principal commentator before Mommsen was the Abbé Claude, of Salmaise, who devoted a thick folio in mediæval Latin to his *Exercitationes* on Solinus, which was printed at Paris in 1629. Several translations of the *Polyhistor* have been published besides Golding's: one in Italian, one or more in German, and one in French. Of these the last mentioned (in 1847) is the least trustworthy. The paper was accompanied by copious explanatory notes and a short bibliographic list of references.

Dr. FIELDING H. GARRISON contributed an account of a Relic of the King's Evil, acquired in 1891 by the Surgeon-General's Library at Washington, U.S.A. It consisted of a folio volume of 22 leaves in which were inserted: (1) a gold "touch piece" of James II.: (2) inventories of moneys disbursed for healing medals; (3) registries of the number of persons touched for the "evil" during the reigns of Charles I., Charles II., and Queen Anne; (4) a reprint of the 1789 pamphlet on "The Ceremonies for the Healing"; (5) the title page of Wiseman's Treatise on the King's Evil (1686) with a portion of the text; (6) "The office of consecrating Cramp Rings, 1694"; and (7) copies of the *London Gazette* for 1705 containing notices relative to the Royal Touch.—Dr. RAYMOND CRAWFURD noted that the volume was interesting because it showed that the compiler knew of the existence of a bronze touch piece of Charles I., for the first public announcement of which in the *Numismatic Chronicle*, 1910, they were indebted to Mr. Henry Symonds. —Mr. D'ARCY POWER added a few additional facts.

CLINICAL SECTION.

Exhibition of Clinical Cases.

A MEETING of this section was held on March 13th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Mr. HENRY CURTIS showed a case of Primary Squamous Epithelioma of the Exterior of the Left Nostril illustrating the Radical Modern Operation. The patient was a man aged 43. A very large skin flap had been turned up, which allowed removal *en masse* of the glands which were extensively involved.

Dr. HILDRED B. CARLILL showed a case of Spastic Smile with Spasm of the Upper Extremity; (?) Huntington's Chorea. The patient was a woman aged 52. At the age of 16, after extraction of two teeth, the lower jaw "came forward" and speech became indistinct. This had remained. Thirteen years ago, three days after confinement, the right arm commenced to shake. Two years ago the patient was first noticed to be always smiling. She was one of five sisters and had no brothers. The family history was negative as regarded a similar complaint or any nervous disease. The smiling facies was worse under observation and on trying to protrude the tongue. The spasm was controlled at times and ceased during sleep. The tongue was large and constantly moving, but could not be protruded normally. Articulation was very imperfect. Swallowing was normal. The optic discs, fundi, and pupils were unaffected, and the cranial nerves were otherwise normal. Motor system: Gait slow and hesitating; no weakness or ataxia of the lower-limbs or of the left upper limb; involuntary contraction of the muscles of the right upper extremity caused a coarse tremor. She had not used her right hand in writing for 13 years, but could perform many movements requiring less accuracy. No mental impairment was present. The sensory system was normal. Reflexes: Arm-jerks exaggerated, the right being greater than the left; knee-jerks exaggerated; ankle-jerks normal; plantar responses flexor; abdominal reflexes not elicited; sphincters normal.

Mr. J. E. H. ROBERTS showed a case of Old-standing Brachial Birth Paralysis with Subluxation of the Shoulder-joint and Anterior Dislocation of the Head of the Radius. It was that of a male patient, aged 17. When he was three days old the right arm was noticed to be paralysed. There was a subspinous dislocation of the head of the humerus and a forward dislocation of the head of the radius. The muscles of the shoulder and upper arm were well developed. The forearm flexors were fairly powerful but the extensors were weak. In the hand the finger-joints were flexed and the metacarpophalangeal joints hyperextended. The thumb was flexed across the palm. The lower part of the forearm and hand was blue and cold. The arm could not be abducted from the side, although the deltoid had recovered. Passive flexion and extension of the elbow were possible through almost the full normal range, but on attempting active movement the biceps, triceps, and forearm flexors all contracted together, so that no movement occurred. Electrical reactions of the shoulder, arm, and anterior forearm muscles were normal. Those of the posterior forearm were very weak but normal. The same was true of the median interossei. The ulnar interossei showed partial reaction of degeneration.

Dr. F. SYLVAN showed a case of Pulmonary Tuberculosis, commencing gymnastic treatment. The patient was a man aged 27. During several months he did not feel well, and in July, 1913, his lungs were declared to be affected. In September he went to a sanatorium and stayed 10 weeks. He then started work, but the next day he had a hæmorrhage and ceased work. A few days later slight hæmorrhage occurred again on two occasions. At the beginning of his stay in the sanatorium his temperature was frequently 100·2° F., but after six weeks it was normal. He now coughed most in the morning and expectorated a fair amount. There were slight dulness on percussion and crepitations over both apices. His vital capacity was 2700 c.c.; inspiratory power, 28 mm. Hg.

Dr. HECTOR W. G. MACKENZIE showed a case of Multiple Carcinomata of Bone. The patient was a married woman aged 45. For nine years she had suffered from "kidney trouble." There had been blood in the urine from time to time and intermittent pain in the right loin. Her medical attendant, suspecting stone in the kidney, sent her to a hospital, where she was admitted. Dr. Mackenzie had been asked to see her on account of swelling and stiffness of both shoulders, and she was then transferred to his care in February last. She began to suffer pain in the right shoulder in March, 1913. The pain gradually got worse and prevented movement in July, 1913. She was uncertain when the left shoulder became affected, but she thought it became so soon after the right. The right elbow also became painful and stiff. The shoulders gradually became swollen and the arms and hands became weak. On examination both shoulders were very prominent in front. The posterior deltoid regions on both sides were swollen, tense, and very tender. No movement could be obtained. There was pulsation over the swellings, which was expansile in character. On the right side the swelling appeared to be most pronounced over the upper end of the humerus. On the left side the swelling was greatest posteriorly in the situation of the scapula. There were stiffness and tenderness at the right elbow-joint. There was much wasting of the muscles of the right arm and forearm, and the only movements possible were those of pronation and supination and the hand movements. On the left side wasting was not so obvious and the elbow could be flexed and extended. A systolic murmur was audible over the swelling on both sides. Loss of flesh had not been observed by the patient until recently. Her face was of a yellowish tint, and there was a pink flush on her cheeks. The spleen was palpable below the costal margin, and the edge of the liver could be felt 2 inches below the costal margin. An X ray examination by Dr. A. Reid showed that the upper part of the right humerus was [illegible]

int

re

un

seat of some nodules of growth. Nothing abnormal was to be seen in the kidney area. The urine was tested for Bence Jones protein with negative results. Blood examination: The erythrocytes numbered 4,281,250 per cubic millimetre, and the leucocytes 9280. The hæmoglobin was 85 per cent. of normal, and the colour index was 1. The differential count of leucocytes was as follows: polymorphonuclear neutrophiles, 46 per cent.; polymorphonuclear eosinophiles, 2·3 per cent.; small lymphocytes, 44·7 per cent.; large lymphocytes, 4·3 per cent.; and large hyaline cells, 2·7 per cent. The distribution of the bone tumours pointed to their being secondary deposits. The most likely seat of the primary disease was the right kidney. If the latter was the seat of growth it must have supervened on an old lesion, probably renal calculus.

Mr. H. W. CARSON showed a case of Malignant Disease of the Male Breast. The patient was a man, aged 65, who had had a growth in the right breast for between seven and eight years, and believed that it followed an injury ten years ago. His work did not cause traumatism to the breast. The condition was one of slow growing scirrhus, forming a tumour centrally placed in the tissue of the right mammary gland, implicating the skin and adherent to the sheath of the pectoralis major. Enlarged glands could be felt in the axilla and posterior triangle of the neck and there was a doubtful nodule in the liver. The case was shown as an example of a somewhat rare condition, but Mr. Carson feared it was inoperable.

Mr. E. M. CORNER showed a case of Fractured Spine of the Tibia. The patient was a young man who early in last December had had his leg hurt while playing football. A heavy man fell on the outer side of the knee of the extended limb. Shortly after the accident the knee became swollen and there was considerable extra-articular swelling of the joint. Abduction of the knee was easy and the tibia could be separated by half an inch from the femur. Flexion of the joint was impossible. On examination all movements of the joint were fair, but flexion was much restricted and painful. The signs and symptoms were such that two surgeons thought that there could be no serious injury in the joint. A skiagram showed separation of the spine of the tibia.

Mr. V. ZACHARY COPE showed a case of Extradural Hæmorrhage causing Slight Aphasia from Pressure over Broca's Convolution. The patient, a man, aged 29, was struck over the left temple in August, 1913. He was unconscious for a time, and had not regained full consciousness when admitted to hospital next day. On admission his pulse was 50 and his respirations 20; he was drowsy, but could be roused. The knee-jerks were slightly exaggerated, and the pupils were equal and reacted normally. There were slight swelling and bruising over the site of injury. In the absence of localising symptoms no operation was considered advisable For some days the condition improved, so that he could answer questions sensibly, but it was noticeable that after giving a sensible answer his speech would tail off into a jumble of disconnected nonsense. Nine days after admission his right pupil became larger than the left and early optic neuritis was found. The pulse still remained 50 to the minute. Operation was undertaken ten days later. The skull was trephined over the anterior branch of the left middle meningeal artery. An ounce or more of old blood-clot was found outside the dura, extending down to the skull base, and two depressed pieces of bone were removed. The dura was not opened. No drainage was employed. Recovery was very rapid after the operation. The speech was soon quite perfect and the pulse normal. He was discharged from hospital just over a fortnight after the operation.

Mr. COPE also showed a girl, aged 14, who had suffered from Sensory Aphasia following an injury, and had recovered after removal of a clot from beneath the dura over the angular gyrus and upper part of the temporo-sphenoidal lobe.

Mr. W. H. BATTLE showed a case of Old-standing Fracture-dislocation of the Cervical Spine. The man, aged 38, was admitted in February, 1914. About four months before admission he fell off his van on to his head, the wheel of the van passing over his left leg. He stayed in bed for two days after the accident, but did not notice anything amiss till about a week later, when he discovered that he was losing power in his hands, and that he often could not extend his fingers after clenching his fist without the help of the other hand. For about one month before admission the patient observed that his legs were gradually becoming weaker, and that he had considerable difficulty in walking. He had had no pain of any description, and there had been no difficulty in controlling the sphincters. He had noticed that his head had become more and more protruded since the accident. When shown his mental condition was normal. The right pupil was larger than the left. X rays showed dislocation of the fifth and sixth cervical vertebræ. Slight general weakness and some spasticity of the muscles of the trunk were present. The tone of the legs was much increased, and the spasticity was out of all proportion to the weakness. There was incomplete loss of appreciation of a pin-prick over the eighth cervical segment, with complete loss below it.

Mr. T. H. KELLOCK showed a case of Deformity of the Long Bones (Osteogenesis Imperfecta). The patient was a boy, aged 4, who had been sent to hospital on account of lameness and bending of the right thigh. He was one of twins, there being nine other children, all healthy, except a sister who had been in splints for knock-knee. The mother and father were both alive and healthy. The children were born at full term; they were breast-fed for three months, subsequently artificially. The twin sister was quite well and had no deformity of bones. For three years the child seemed quite well and walked well. A year ago he fell down stairs and "bent" his right leg above the knee; pain and swelling of the part resulted, but he was able to walk for a few days after the accident. Three months afterwards it was put on a splint, which had been used ever since—for about seven months. The child now had the appearance of suffering from rickety deformities of the bones, the skull was large and the frontal eminences were prominent; the chest was flattened from side to side, and there was well-marked "rickety rosary." Both femora, the right especially, showed antero-posterior curvatures at the junction of middle and lower thirds. The tibiæ were flattened from side to side and curved forwards towards the lower ends. Thickening could be seen and felt at most of the epiphyseal junctions. Skiagrams showed marked attenuation of the long bones and the bones of the tarsus; there was very little compact tissue, and the medullary tissue was almost "spider-web"-like in appearance. There was no obvious fracture at the seat of the bending in the right femur. The child's general condition was good and he had good teeth.

Dr. R. O. MOON showed a case of Aneurysm of the Ascending Aorta. The patient's family history was unimportant. There was no history of any rheumatic affection. A miscarriage occurred at the age of 25. About seven years ago she realised that her heart was diseased in some way; she suffered from palpitation, shortness of breath, choking sensations, and occasional pains in the left mid-axillary line. About ten months ago she noticed a swelling in the upper part of the chest, with throbbing sensations and pain over it. There was a bulging of the three upper right ribs at their sternal ends, extending for 9 cm. from the mid-line. Over the swelling there was a well-marked systolic thrill and there were harsh systolic and diastolic murmurs. The apex beat was diffuse in the seventh space and displaced outwards. To-and-fro murmurs were heard all over the præcordial area. The pulses were equal, markedly collapsing, and their rate 100. The blood pressure was equal to 172 mm. Hg. The pupils were equal, and there was neither dysphagia nor tracheal tugging. The Wassermann reaction was positive.

Mr. P. P. COLE showed a specimen from a case of Tumour of the Thigh. The sections exhibited concerned a case of tumour of the thigh which was shown at the November meeting of this section. The tumour developed after a fracture of the femur, but the history suggested that an endosteal tumour was present before fracture occurred. It was suggested that radium might be tried with advantage. Accordingly, 200 mg. were embedded in the tumour and allowed to remain for 24 hours. The constitutional effect was considerable, and the patient's general condition was seriously impaired. Radium was applied externally during the course of two months. A sinus persisted at the site of introduction, and the tumour became slowly but steadily larger. The patient was reluctant to lose his leg, but eventually consented. Amputation through the hip-joint was performed in January last. Spinal anæsthesia was used to guard against shock, and because the patient was the subject of marked aortic regurgitation. The type of operation was an anterior racquet, only just sufficient of the thigh being left to furnish flaps. There was no shock, and recovery had been uninterrupted. The sections were of the tumour itself and of an enlarged gland removed from the inguinal region, and showed microscopically the structure of a myxochondroma.

Mr. COPE contributed a short paper on Traumatic Sensory Aphasia.

SECTIONS OF NEUROLOGY, OPHTHALMOLOGY, AND OTOLOGY.

Resumed Discussion on Nystagmus.[1]

THE third combined meeting of these sections was held on March 11th to conclude the debate on Nystagmus. The chair was occupied by Mr. RICHARD LAKE, the President of the Section of Otology.

Dr. WILFRED HARRIS said that nystagmus should not be assumed to exist unless the lateral movements were persistent and rhythmical during the test; the observer should also determine whether the nystagmus was a symptom of cerebro-spinal disease or was of ocular origin. Cases which did not belong to either of these groups, such as head-nodding, should also be recognised, and in the last-named form usually only one eye was affected. If in early infancy macular development was interfered with, such as by anterior polar cataract, so that there was not a clear image on the fovea, the cerebral coördination was not brought into play to keep the eye rigid; hence there were constant oscillatory movements. Ocular nystagmus might be said to be due to disease of the afferent path concerned with the reflex for fixation of the eyeballs. Occasionally in adults nystagmus might be due to defect of vision, and it might be uniocular. In nystagmus of central origin the symptom was brought out, especially on deviation of the eyes laterally or upwards, and was not apparent on fixation in the median line. Most intense nystagmus was occasionally set up by a tumour of the cerebrum, especially if the optic thalamus were involved by it. He mentioned cases of this, and recalled that Gowers made the same observation. The value of nystagmus for cerebral localisation was not great, but it was usually suggestive of cerebellar disease. The most intense nystagmus might be an accompaniment of subtentorial disease.

Dr. A. ABRAHAMS explained the *modus operandi* followed by him in obtaining kinematographic records of nystagmoid movements. He said the human eye was a very capable micrometer and was capable of appreciating a movement which the camera did not reveal. Some of the movements photographed were less than one-tenth of a millimetre, and pictures were taken at the rate of 25 to 30 per second. Miners' nystagmus was too fine to photograph.

Mr. J. F. O'MALLEY dealt with two great types of nystagmus, ocular and vestibular; and exhibited tables of useful subclassifications, with suggestions as to etiology.

Mr. HAROLD B. GRIMSDALE spoke of his experiences with cases at the Royal Normal College for the Blind. Half the cases of nystagmus there had had ophthalmia neonatorum; and there were a large number of cases in which the nystagmus followed an accident to the cornea. Up to the age of 5 any severe disturbance of the cornea seemed to be followed by nystagmus. But the blind principal, who lost his sight at the age of 4 following measles, showed no nystagmus. It was said that nystagmus never occurred in blind children, but he quoted a case to the contrary; the patient, a child, later recovered a fair degree of vision, and the presence of the nystagmus led him to hope that that might be so.

Mr. A. B. CRIDLAND dealt with the question of the restriction of the fields of vision for red, blue, and white in subjects of miners' nystagmus; this could be observed in the early stage and the improving stage of the condition. He possessed some 70 charts to illustrate the fact that in practically all cases contraction existed for red, blue, and white, but it was of the concentric type, and more or less symmetrical in shape. Occasionally there was an interlacing of the three fields. The restriction might persist even months after both subjective and objective signs had disappeared. Most of the cases showed blepharospasm, neck twitching, &c. The changes in the fields were akin to those seen in functional disease, and that lent support to the view that miners' nystagmus was a nervous condition.

Mr. ANGUS MACNAB spoke of the relative importance of the rods and cones in different degrees of illumination. With light reduction the rods became the more important until the threshold of stimulation of the cones was passed. In the macula there were only cones, no rods, and after an eye had been subjected to low illumination, it gradually became adapted to its environment, and passed into a condition of dark adaptation. Miners' nystagmus was noticed to be most prevalent where the coal was most absorbent of the little light there was; and the fixation of the subjects was in a state of very unstable equilibrium. The concentration of the miner on his blows also helped, in these circumstances, to produce the neurosis. He thought the influence of refractive error in the causation of nystagmus must be very small, though errors of muscle balance might have some weight. It would be interesting to ascertain what proportion of affected miners suffered from heterophoria.

Mr. T. B. LAYTON said there were great differences of opinion as to the value of vestibular nerve tests, including nystagmus, in the diagnosis of nerve diseases. He raised the question as to how much of failure to perform correctly coördinate muscle movements was due to withdrawal of cerebral control, and how much to defect of the vestibular nerve. He was convinced that in a certain number of cases vestibular reactions when correlated with evidence obtained from other sources would enable one to clinch a diagnosis, or detect a gross lesion which otherwise would seem equivocal. He thought every neurologist should learn to do these tests, or send their patients to otologists who could do so.

---

[1] THE LANCET, March 14th, 1914, p. 748.

Dr. A. RUGG GUNN spoke of nystagmus as it affects albinos. In diseases of the retina associ [illegible] rods there was the converse [illegible] An eye in that condition lookin [illegible] found the red end shorten and [illegible] portion appeared to move towards the violet end. It occurred to him that if in the albino the cones were found to be functionless, this absence of function in the fixation point was a sufficient cause for the nystagmus, and also, perhaps, for the intense photophobia found. Such a person would be dark-adapted. He described the case of an albino, one of nine observed, in which this was so.

Mr. G. J. JENKINS spoke of labyrinthine nystagmus in its relation to various canals, and Mr. PARSONS asked whether the albino described by Dr. Gunn was colour-blind, because totally colour-blind people showed the characteristics described.

Mr. W. T. HOLMES SPICER, Dr. JAMES TAYLOR, and Mr. SYDNEY SCOTT replied, and the PRESIDENT suggested that perhaps a committee of representatives of the three sections might present definite conclusions from the various points of view.

SECTION OF PSYCHIATRY.

Definition of the Sexual Instinct.

ON March 10th members of the British Psychological Society were guests of this section. The chair was occupied by Sir GEORGE SAVAGE, the President.

Dr. WILLIAM MCDOUGALL read a paper on the Definition of the Sexual Instinct. He was of opinion that the present attitude of both academic and medical psychologists on the nature and rôle of instinct in general, and in particular the instinct of sex, was chaotic; and it was only by coöperation of medical with other psychologists that a right understanding of sex instinct could be hoped for. The great authorities, whose names were familiar to all who were read in the literature, were far from agreed on the matter, while the hesitation shown in accepting hypotheses seemed to argue a lack of understanding of the leading facts. Those who turned to the standard works on psychology for an authoritative statement on the part played by the sex instinct in human life were disappointed. Even William James, who fully recognised the value of human instincts, scarcely touched on that of sex. There was a perpetuation of the error that instinctive action was merely compound reflex action. The erroneous views could be classified into two groups: (1) those which were unduly simple, representing the sex instinct as merely the tendency to respond to certain disagreeable sense-stimuli with movements which abolished the disagreeable and procured pleasurable sensations; and (2) those which ascribed to the sex instinct a variety of mental and bodily processes which originated in other and distinct roots. A prevalent error was to confound the parental with the sex instinct, and this he considered was largely due to the ambiguous employment of the term "love," as well as to certain similarities of behaviour prompted by these instincts, and the biological ends served by them. Some authors also—erroneously, as he contended—considered modesty, jealousy, and masochistic and sadistic tendencies to be components of the sex instinct. The Freudian doctrine comprised several errors. Against the view that the sex instinct arose from the desire for pleasurable gratification was the fact that in some cases the instinct continued after complete castration. He strongly disagreed as to Freud's contention that the sex instinct was normally present in infanc [illegible] its earliest beginnings at about the [illegible] gressed steadily to puberty. Thougl [illegible] admittedly complex, it must not be r [illegible] two distinct impulses. Though he criticised some of Freud's contentions, he paid a high tribute to his work in the domain of psychology.

A communication from Dr. C. MERCIER was read, in which he re-stated his beliefs as expressed in his work on "Conduct," and drew an illuminating analogy between human instincts and those manifested by the lower animals.

Dr. A. ERNEST JONES wrote pointing out that Freud carefully distinguished between the numerous physical and mental processes which were preparatory, and those which represented the culmination of gratification; he drew a line of difference between processes "for pleasure," and those "in pleasure," the former not being regarded as necessarily sexual. He criticised Dr. McDougall's statement that the grounds of the assumption that the sex instinct was normally active from the earliest years of infancy would not bear examination. He instanced early masturbation, and saw no reason why a line should be drawn and the statement made that before a certain age acts were not sexual, but they were afterwards. The sexual, like all other functions, pursued a tortuous development until adult life. And he saw no necessity to differentiate between the parental and the sex instincts.

Professor W. BROWN pointed out that Freud's ideas were based, not on *a priori* considerations, but on careful psycho-analysis. At first one felt somewhat repelled by Freud's doctrines, but if, as was necessary, one treated his language metaphorically one saw much more clearly. The study of dreams was also very helpful.

Dr. M. D. EDER also defended Freud, and considered that the parental and the sex instincts were closely allied. It was difficult to know exactly at what age the sex instinct commenced, and those who practised psycho-analysis did not agree about it. He thought Dr. McDougall had in his paper looked only backward, and hence ignored the strong aspirative power in man.

Mr. SHAND pointed out how diverse were the meanings attached to the word "instinct." He thought it might be defined as an inherited disposition, excited innately by certain stimuli and invoking innately, in response, certain specific types of behaviour, and he proceeded to elaborate this thesis by observations on the lower animals.

Dr. D. FORSYTH also spoke and Dr. MCDOUGALL replied.

LIVERPOOL MEDICAL INSTITUTION.

Preliminary Report of the Special Committee on Venereal Diseases.—Ambrose Paré: His Work and Times.

AT the clinical evening of this institution held on March 5th, Dr. E. W. HOPE, the President, in the chair, a large number of cases were shown by the members.

At the request of the PRESIDENT, Professor R. J. M. BUCHANAN read a short Preliminary Report of the Special Committee on Venereal Diseases, detailing the work done by the committee up to date.

Dr. C. RONEY SCHOFIELD read a paper on Ambrose Paré, His Work and Times. He said: The progress of medicine was slow from the time of Hippocrates, born 450 B.C., who was our first physician. His work was the medical authority for the next 1500 years. Theology and Medicine were interwoven inextricably, and every doctor came from the ranks of the Church. Quacks abounded. The leading school of medicine in the fourteenth century was at Montpellier. Barber-surgeons were introduced by the physicians, who, being priests, could not shed blood. They were licensed to bleed and do what was now termed minor surgery. Ambrose Paré appeared in the sixteenth century, born at Laval in Mayenne. His last descendant died at Laval on March 6th, 1852—a maiden lady. After surmounting the difficulties that poverty and lack of influence put in his path Paré became a licensed barber-surgeon. He made his reputation in the wars which at that time France was continually engaged in. He was contemporary with Vesalius and Harvey, but lived 13 years after the death of Vesalius and before Harvey was born. Modesty characterised his writings: "I treated him, God cured him," was his favourite phrase. He was responsible for the [illegible] of treatment of wounds and the successful [illegible] He also introduced [illegible] itted a member of the [illegible] edicated his second volume to Henry III. of France and the first to Lord Herbert of Cherbury, in 1579 and 1575 respectively. His dissertation on the humors explanatory of the then elementary appeared healthy, but had a patch of tuberculous deposit near it, while the left showed only slight hyperæmia. The urine from the latter, however, was of low specific gravity and contained tubercle bacilli, while that from the former was normal. A markedly tuberculous left kidney was removed and the patient did well. A tuberculous condition was sometimes masked by a bacillus coli infection, as in a case referred to. Tuberculin treatment had been very successful in the case of a woman who was found by catheterisation to have only one functioning kidney, and that tuberculous.

WIGAN MEDICAL SOCIETY.—A general meeting of this society was held on Feb. 20th, Dr. John Thomson Shirlaw, the President, being in the chair.—Dr. R. Prosser White opened a discussion on the Control of Syphilis. Dr. White gave as heads of his subject the following: (1) That the profession in this country had shirked its responsibility; (2) that the public was ignorant; (3) that dermatologists had forced the matter into the light of a public inquiry; (4) its prevalence and ravages; (5) it should take precedence of tuberculosis; (6) the methods of dealing with it in other countries; (7) should it be notified, if so, how? and (8) the one way of control. Dr. White did not take these divisions in the order given, but they formed the framework of his paper. He held that it was largely due to the apathy of the profession and the ignorance of the public that they in this country were in such a backward state as regards the recognition and treatment of syphilis, that dermatologists had been keeping the matter in the foreground for years, and that it was largely due to their efforts, here and in other countries, that such progress as could be recorded was made. In Great Britain there were practically no statistics outside the army and navy. They were lamentably behind other nations. The Scandinavians were far ahead of them, syphilis being a notifiable disease in Denmark, Sweden, and Norway. In Russia it had been notifiable for a long time, and supervision was very strict. In their own colonies the matter was being taken up, and Australia was at present legislating on the subject. In New York State all information respecting the persons suffering from the disease was compulsory, save the name and address, and Wassermann and other reactions were made free. The incidence of syphilis was very wide. In Copenhagen 28 per cent. had venereal disease; in Berlin (Erb) 12 per cent. were syphilitic; in Paris (Fournier) 15 per cent.; and in Norway 11 per cent. of all males were suffering from syphilis. Byrom Bramwell stated that 75 per cent. of those who contracted syphilis eventually died from it. It was responsible for 40 per cent. of all cases of insanity (Mott). Possibly with the exception of malaria syphilis was the cause of more deaths than any other disease, taking the world through. In New York, French says, there were 50 000 fresh cases annually, and probably 70,000 in London. Treatment was free in Sweden and Norway, but it was not thorough. In Denmark treatment was compulsory and free, and neglect of treatment was an illegal act, and therefore punishable. In Rome it was treated by dispensaries, State supported. The law in this country left syphilis severely alone. The communication of any other contagious disease could be punished by law; not so syphilis, the most serious of them all. It was almost neglected by the public health and the Poor-law authorities. Dr. White expressed the opinion that notification of some kind ought to be made compulsory, and that the only way to control the disease with any chance of success was that treatment should be free, generous, and, if necessary, compulsory.—The President mentioned that the Wassermann reaction could not be obtained in the early stages, and that the best early test was the microscopical examination of serum from the sores.—Mr. M. G. McElligott mentioned the extraordinary knowledge of syphilis, its origin and treatment, &c., shown by the public as well as the profession in St. Petersburg.—Dr. M. Benson thought one of the reasons why more was not known of the disease in this country was that the treatment was largely in the hands of herbalists, charlatans, and quacks. He was of opinion that both parties contracting or spreading syphilis should be punished and that the disease should be notified.—Dr. T. Campbell stated that the International Medical Congress had put forward two propositions: (1) That syphilis be notified, names of persons suffering not disclosed; and (2) that there be depôts for serum reactions and treatment. He referred to the limitations of "606," and its inability to penetrate to the central nervous system, and said that in London 40,000 cases were seen and treated every year.—Dr. F. E. Wynne said the reason the State did not take the matter up was largely due to Mrs. Grundy. That lady did not believe in facing facts, and the "State regulation of vice" stank in her nostrils.—Dr. J. Blair mentioned the enormous prevalence of syphilis in Southern Russia and the knowledge of the best forms of treatment among the laity, and quoted from the *British Medical Journal* the statement that syphilis was responsible for 33 per cent of pathology and gonorrhœa for 50 per cent. of gynæcology.—A vote of thanks was unanimously passed to Dr. White, who, in replying, referred to many of the points raised during the debate, specially laying stress on the fact that syphilis was very amenable to treatment, which, however, must be thorough and prolonged. The control of tuberculosis was a question of housing, that of syphilis a question of treatment.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on March 13th, the President, Dr. A. K. Chalmers, being in the chair, when a paper was read by Dr. A. S. M. MacGregor, tuberculosis officer of Glasgow, entitled "Studies in the Epidemiology of Phthisis." After pointing out the great difference in various towns in respect of the proportion of notifications to deaths, due apparently to the varying clinical standards, Dr. MacGregor said that it had been the experience in Glasgow that many notifications were of doubtful value, and that for the purpose of testing the accuracy of notifications as well as of getting into touch with practical issues he had endeavoured to follow the cases notified in 1910 during the three succeeding years. Of the 3425 cases notified in 1910 nearly 53 per cent. of the patients had died, though 2 per cent. were certified as having died of a disease other than tuberculosis. 30 per cent. had either left the city or could not be traced. Of the remainder 13·9 per cent. were at home and 2·3 per cent. in institutions. Referring to contacts Dr. MacGregor said that it was regarded as an axiom in anti-tuberculosis work that the members of a family where a case of phthisis had occurred should be subjected to medical scrutiny for the detection of other or early cases in the same household. Records had been kept in Glasgow of the incidence of phthisis in the immediate contacts of cases already under notice. Comparing the number of secondary cases which were found with the number that might be expected from the attack rate of the whole population, there was a difference of only about 1 or 2 per cent., the cases being actually 63 per annum more than might have been expected. These results Dr. MacGregor considered did not indicate that the setting up of elaborate administrative machinery for the examination of contacts would be attended by the discovery of more than a relatively small proportion of the cases which occurred in the course of the year.—Dr. W. G. Willoughby stated that in Eastbourne he received about five times more notifications of cases of phthisis than there were deaths from the disease. He emphasised the importance of following up notified cases.—Dr. R. Veitch Clark considered that inquiries should be made into the mortality rate of those cases which had had only six months' treatment. He was of opinion that better results would follow from more prolonged treatment than was usually given.—Dr. E. W. Hope thought that at least one-half of the value of institutional treatment lay in the isolation and removal of infected persons. He deprecated the putting forward of inflated hopes with respect to the treatment of phthisis—a practice which was not adopted as regards other diseases.—Sir Shirley Murphy hoped that information would be forthcoming as regards the social position of those contacts who were infected, and thought that probably it might then be found that among the lower classes the expected and actual figures would not be very far apart.—Dr. P. Caldwell Smith considered that greater energy should be directed to tuberculous children, when much better results would be obtained.—Mr. E. H. T. Nash said that in Wimbledon he received two notifications to one death. He asserted that it was two months after a case had been diagnosed before the patient could be got into a sanatorium under the National Insurance Act, whereas a Post Office employee was sent to an institution in a week.—Dr. Alfred Greenwood was certain that when tuberculosis dispensaries had really got into working order the results as to the future working capacity would be much more favourable than they were at present.

MANCHESTER MEDICAL SOCIETY.—At a meeting of this society held on March 4th Dr. W. Wilson read a paper on the Relation of Throat and Nose to Some Diseases met with in General Practice. He expressed the opinion that the generally accepted views regarding the function of the erectile tissue of the nose were incorrect. The lining mucosa of the air sinuses, he said, warms and moistens the inspired air providing this mucosa is healthy. The erectile tissue can be removed and no harmful effects will follow. The anterior portion of the middle turbinal is of extreme importance in this respect, as it is full in the line of the inspiratory stream. Nasal suppuration is one of the chief causes of pneumonia, broncho-pneumonia, and flatulent dyspepsia. Influenza, gout, and rheumatism are the commonest causes of throat and nose troubles. Influenza, tonsillitis, acute rheumatism, and some forms of appendicitis are all manifestations of the same infection. The tonsils should be completely enucleated if at all affected in acute or chronic rheumatism. In children the tonsils and any adenoids present should be removed on the first signs of nervous irritability, anæmia, and "growing pains"; this will prevent most of the severe cardiac affections of childhood. "Neuroses" of the upper respiratory tract can usually [illegible] 's should not [illegible] A. Mumford [illegible] Stamina of Children for School Purposes. He began by emphasising the necessity of distinguishing physique, which was really structure, from stamina, which, he said, is the sustained capacity to utilise the structure and put forth mental and physical energy. The problem increases with adolescence as the structure is incomplete and future capabilities are unknown. The various methods adopted in the past are suitable only for estimating the bodily growth and for nutrition. Pignet's factors and Oppenheimer's formulæ were discussed; also factors derived from an examination of the reports of the anthropometric committee of the British Association. The limitation of estimates obtained by medical examination of individual organs was dealt with. Methods of calculating physique were described. Dr. Mumford concluded his paper by a description of the work accomplished at the Manchester Grammar School.

NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at the Western Skin Hospital on March 12th, Dr. David Walsh being in the chair.—The following were among the cases shown:—Dr. Walsh: A case of Recent Deafness being treated by intravenous injections of neosalvarsan. There had been found a positive Wassermann reaction and there were traces of long-healed dermato-syphilides.—Dr. G. N. Meachen: Recurrent Œdema of the Right Cheek without definite cause. As the result of the discussion a further examination of the teeth and antrum would be undertaken.—Dr. Alfred Eddowes: A completely generalised Acute Eczema which appeared to be due entirely to external infection. It began a year ago as a bicycle rash, spread to the groins, then to other folds, and finally burst out all over the entire skin. All the lymphatic glands were swollen, the skin red, swollen, and so irritable as to prevent sleep. A pure culture of staphylococcus albus was found in vesicles on the palm. Recovery was rapidly taking place under mild antiseptics and vaccine injections.—Mr. H. C. Samuel: 1. A case of Spontaneously Ulcerating Nævus in a very young child. After the trial of many dressings it was healing under liquid paraffin covered by gauze containing a very mild solution of perchloride of mercury. 2. A case of Leucodermia affecting the centre of the right eyebrow, the centre of the upper eyelid, the right cheek, temple, and the side of the mouth.—In the discussion that followed Dr. Walsh laid stress on the fact that the child had suffered long and severely from toothache on that side.—Dr. Eddowes recalled a case of leucodermia which supported that contention.

ADMINISTRATION OF THE MENTAL DEFICIENCY ACT.—Sir William Byrne, chairman of the Board of Control under the Mental Deficiency Act, is announced to read a paper before the London District Poor-law Conference on May 11th on "The Administration in London of the Mental Deficiency Act."

Reviews and Notices of Books.

Sanatoria for the Tuberculous, including a Description of many Existing Institutions and of Sanatorium Treatment in Pulmonary Tuberculosis. By F. RUFENACHT WALTERS, M.D. Lond., M.R.C.P. Lond., F.R.C.S. Eng., Joint Tuberculosis Officer to the Surrey County Council. Fourth edition. London: George Allen and Co. 1913. Pp. 445. Price 12*s.* 6*d.*

OWING to the vast extension of the antituberculous machinery in various parts of the civilised world the author has deemed it necessary to rewrite the present edition. He has also taken advantage of the opportunity to give a more complete description of the principles and methods of sanatorium treatment. Unfortunately, the term "sanatorium treatment" has given rise to much misapprehension, the idea being rife, not only amongst the laity but also amongst practitioners, that whenever an individual is suffering from pulmonary tuberculosis, no matter what type the disease may present, he or she ought to go into a sanatorium. Consequently this form of treatment has been somewhat discredited, not by a failure on the part of the treatment, but on account of the totally unsuitable cases which have been sent to the various institutions.

Dr. Walters, in discussing the scope of sanatorium treatment, states that although originally intended for early and easily curable cases, it has been found impossible to limit admissions to this class. He suggests that a modern sanatorium requires at least two more or less separate departments, one for the rest cure of those who are feverish or otherwise unfit for exercise; and another for physical training by graduated exercise. We believe that better results would be obtained and that confidence would be again restored if only those patients were sent to sanatoriums who are able to take exercise and be out of their beds most of the day; febrile cases being treated at other institutions or at home if the circumstances are favourable. We quite agree, however, with the remark that mere pleasure seekers and those who will not submit to a regulated life are best excluded. Several chapters are devoted to a consideration of sites and climates suitable for the erection of sanatoriums, and the construction, decoration, and necessary furniture for such institutions are duly discussed.

The remarks on sanatorium treatment and its results are worthy of careful study. As Dr. Walters remarks, if the fresh-air treatment merely consisted in letting every patient rest in the open air, or follow his own inclinations as to the amount of exercise, it would be an exceedingly simple matter, scarcely requiring medical supervision. But the essence of sanatorium methods is the elimination of haphazard treatment and the prescription of absolute repose or of various degrees of exercise, according to definite medical indications. Details are given of the daily life to be followed by patients suffering from pulmonary tuberculosis, stress being laid on the differences to be observed in febrile and afebrile cases respectively. The chapter on rest and exercise for the afebrile is a good summary of the principles which should be followed.

In speaking of the results of treatment Dr. Walters shows how difficult it is to obtain accurate statistics. He rightly points out that these results depend on three factors: on the nature of the case, the nature and circumstances of treatment, and the appeared healthy, but had a patch of tuberculous deposit near it, while the left showed only slight hyperæmia. The urine from the latter, however, was of low specific gravity and contained tubercle bacilli, while that from the former was normal. A markedly tuberculous left kidney was removed and the patient did well. A tuberculous condition was sometimes masked by a bacillus coli infection, as in a case referred to. Tuberculin treatment had been very successful in the case of a woman who was found by catheterisation to have only one functioning kidney, and that tuberculous.

Wigan Medical Society.—A general meeting of this society was held on Feb. 20th, Dr. John Thomson Shirlaw, the President, being in the chair.—Dr. R. Prosser White opened a discussion on the Control of Syphilis. Dr. White gave as heads of his subject the following: (1) That the profession in this country had shirked its responsibility; (2) that the public was ignorant; (3) that dermatologists had forced the matter into the light of a public inquiry; (4) its prevalence and ravages; (5) it should take precedence of tuberculosis; (6) the methods of dealing with it in other countries; (7) should it be notified, if so, how? and (8) the one way of control. Dr. White did not take these divisions in the order given, but they formed the framework of his paper. He held that it was largely due to the apathy of the profession and the ignorance of the public that they in this country were in such a backward state as regards the recognition and treatment of syphilis, that dermatologists had been keepin the matter in the foreground for years, and that it was l ely due to their efforts, here and in other countries . progress as could be recorded was made. ce that as a stude written in the form of lectures always proved a refreshing oasis in the desert of an examination "grind," so much so that he resolved to cast his own text-book of nervous disease in that form. He has, however, attempted a compromise by the inclusion of tables of symptomatology and of differential diagnosis, and by the addition of a very full index to the subject matter of, and incidental allusions in, the lectures. Without discussing the question of whether the disadvantages of the lecture type of text-book do not outweigh its advantages, we may say at once that these lectures of Dr. Bing are very readable and lucid, that they cover the whole field of neurology, perhaps a little unequally, and that they bear witness to the author's clinical experience and erudition.

The chapters are arranged under such general headings as diseases of the peripheral nerves, the dyskinesias, pathological conditions characterised by spasticity, acute infective nervous diseases, syphilitic nervous diseases, encephalorrhagia and encephalomalacia, arteriosclerosis, infantile hemiplegia and diplegia and Little's disease, cerebellar diseases, dysglandular symptom-complexes. An arrangement of this sort presents certain features that are obviously open to objection. Thus the common condition of hemiplegia, to take but one instance, is subdivided and spread over several separate headings; there is, as it were, a cross division of the subject instead of a longitudinal. We should think that the originality and suggestiveness of the book would be best appreciated by those who already have a fair knowledge of neurology as a whole. In a book which describes itself as a "Lehrbuch" we should like to see references to the symptomatology of the uncinate region; this appears to have been overlooked. Among the types of crossed hemiplegia there is no reference to the type with hemiplegia on one side and blindness in the contralateral eye. We cannot find adequate description of the rôle of the spirochæta in general paralysis. The allusion to myotonia atrophica is

System of Ophtha[illegible], though 2 pe Walter L. Pyle, of Phila se other Darier's "Ophthalmic Therap[illegible]" and Mayou's "Pathology and Bacteriology of the Eye," already reviewed in our columns.

It must have occurred to many teachers of ophthalmology to write a text-book dealing with diseases of the eye from the standpoint of signs and symptoms. It is the aspect of the subject which is presented to the surgeon and student by every case he sees. Yet it is not surprising that so difficult a task has not hitherto been seriously attacked. Only those of very wide clinical experience could attempt it, and to them the time necessary for carrying out the project is usually lacking. Dr. Beard has made a valiant effort, but it must be admitted that the result is not completely successful. The book is divided into two parts, of which the second is devoted to the fundus oculi and consists of eight chapters or 180 pages. The first nine chapters, or 196 pages, suffice for all the diseases of other parts of the eye. Such an unequal division of the subject carries its own condemnation, and it is only the portion dealing with fundus conditions which can be said to be adequate. This part is really well done, and the beautiful coloured plates and numerous black-and-white illustrations in themselves make up a desirable ophthalmoscopic atlas. Even here, however, the author uses space which he can ill afford for theories of detachment of the retina and so on, problems of great interest but not immediately germane to semeiology. In the first part, where space was still more valuable, we find pages devoted to elaborate classifications of cataract and the theories of its causation, while important subjects like interstitial keratitis and cyclitis are dismissed in a few words.

The book is well printed, with the exception of a few Greek derivations, almost all of which contain misprints. It is worth buying for the illustrations and the text of the part devoted to the fundus oculi.

A Text-book of Physiology for Medical Students and Physicians.

By WILLIAM H. HOWELL, Ph.D., M.D., Sc.D., LL.D., Professor of [illegible] Hopkins University, Baltimore. [illegible] revised. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 1020. Price 18*s.* net.

THE advances in all departments of physiology are so rapid that to select and to add to the text of a well-considered and approved work on physiology, such as the one before us, the significant and salient new facts that have been discovered during the past two years is no easy task. We think the author has succeeded, as in former editions, in keeping his text-book abreast of current investigations. Since the publication two years ago of the fourth edition, which was reviewed in THE LANCET of Dec. 16th, 1911, p. 1707, material advances have been made in physiological chemistry, and more especially in that department which deals with the details of intermediary metabolism. Moreover, our increased knowledge of the specific functions of the different proteins in the growth and the maintenance of the body has opened up a new path, which bids fair to be of fundamental importance in dietetics. In this connexion the exposition of the author on such subjects as the nutritive value of different proteins, the specific dynamic action of proteins and vitamines is terse, illuminating, and suggestive. Here and there we find additions to the literature quite up to date, so that the advanced student can, by consulting this book, pursue in greater detail the subject he is interested in.

Substantially this edition, in all its arrangements and essential details, is like the last edition with here and there some new matter judiciously added so as practically not to increase the bulk of the volume. So far as the actual number of pages is concerned the increase amounts to only two pages, while the number of illustrations is practically the same in both editions. The book remains a safe and comprehensive exposition of the present state of our knowledge on physiological matters in application to medicine.

Konstitution und Vererbung in ihren Beziehungen zur Pathologie.

Von Professor F. MARTIUS. With 13 illustrations in the text. Berlin: J. Springer. 1914. Pp. viii.-258. Price 12 marks.

THE year 1914 is to be marked by the publication of the first half dozen volumes of a new series of German medical text-books. They are to form an "Encyclopædia of Clinical Medicine," edited by Professor Langstein, Professor von Noorden, Professor von Pirquet, and Professor Schittenhelm. Each is to combine clinical science with clinical practice; each will be complete in itself, a full and authoritative exposition of its subject; together, the separate manuals are to cover the whole field of clinical medicine, both general and special. This, the first volume to appear, deals with constitution and inheritance, and gives as clear an account of those much misused terms as one may hope to find. Professor Martius writes at full length, quoting freely and freely criticising many of the authors who have busied their pens with this subject before him. He confines himself to general principles, and but rarely falls back on their practical applications in daily life. Thus he has singularly little to say on the subject of inheritance in tuberculosis, the familial predisposition to phthisis. [illegible]
sine quâ [illegible]
commone [illegible]
persons; for the rest, his few isolated references to this important subject leave it unilluminated.

The book is well written, thoroughly indecisive, and perhaps inevitably so. One rises from its perusal with a feeling of the unreality pervading much that has been written about constitutions, diatheses, family tendencies, and the like, terms that so conveniently cloak ignorance and stem the tide of research into the obscurities of causation in disease. Professor Martius has produced an interesting volume, and it may be warmly commended to the attention of all medical philosophers.

Chirurgie Générale et Chirurgie Orthopédique des Membres.

Par PL. MAUCLAIRE, Professeur Agrégé à la Faculté de Médecine, Chirurgien de la Charité. Avec 317 figures dans le texte. Paris: J. B. Baillière et Fils. Pp. 542. Price, paper, 10 francs; boards, 11.50 francs.

THIS is another volume of the excellent Nouveau Traité de Chirurgie, edited by Professor A. Le Dentu and Professor Delbet. From the title of this volume it will be seen that it covers a large area. The first section deals with the subject of traumatism of the limbs, and the second treats of the infections. In the third section the tumours of the limbs are considered, and here it may be noted that the author has included the tumours of the shoulder girdle and of the hip girdle; this is as it should be, as both embryologically and pathologically these are essentially parts of the limbs. It is probable that the most valuable part of the volume is that dealing with deformities, for, indeed, these must always form a very large portion of the conditions in the limbs requiring surgical treatment; here we see the author at his best, and the wealth of illustration, when added to the clearness of the descriptions, renders the book a most valuable treatise on this important subject.

We may draw attention to the account of the surgical treatment of infantile paralysis. This is always a very difficult subject, and the number of methods that have been devised for treating the deformities resulting from these paralyses is very great; but Professor Mauclaire has succeeded in putting very clearly the various procedures at the surgeon's command, and his advice as to the choice to be made is judicious.

The Administrative Control of Small-pox.

By W. McC. WANKLYN, B.A. Cantab., M.R.C.S. Eng., D.P.H. London: Longmans, Green, and Co. 1913. Pp. 86. Price 3*s.* 6*d.* net.

THIS is a companion volume to the useful little work by the same author entitled "How to Diagnose Small-pox," which was reviewed in THE LANCET of Oct. 25th last year. Mr. Wanklyn tells us that it was drafted primarily for post-graduate students reading for the Diploma in Public Health, but we agree that it will also be found useful by those who have to deal with outbreaks of small-pox.

As in his former work, Mr. Wanklyn adopts a conversational style, and his talk to his readers is that of a health officer with special knowledge of the disease, who knows how to impart the essential matters which he has learnt by experience. The book is all that can be desired as a guide to the student on the methods of control adopted in London and in large centres of population where there is an extensive and well-organised sanitary equipment which includes a first-rate ambulance service and a sufficiently isolated small-pox hospital kept at all times in readiness. As a practical guide to the medical officer of health of a smaller provincial town or rural district it is rather less satisfactory. Here, when the medical officer has a casual case or two of small-pox to deal with, he may be quite unable to "telephone the case away," or "dispatch his staff to make inquiries," or to do other things which come so easy in the metropolis. But he need not on that account consider himself on the brink of disaster if he keeps in mind a few simple principles based on the elementary facts of small-pox and vaccination and applies them to the circumstances. In this connexion we note that Mr. Wanklyn includes, as the seventeenth proposition of small-pox administration, that reports should be sent to the "proper authorities." It is well to be specific; the authorities in question are the Local Government Board and the county council, and the medical officer of health in the circumstances to which we refer would find it advantageous to reckon reporting to these bodies among the first of his duties. However well he may have the matter in hand, a valuable reserve force will then be behind him.

The author rightly lays stress on the necessity of keeping small-pox in mind in inter-epidemic periods, and being always on the watch for its unexpected appearance. But it is going rather far to recommend every medical officer of health to have reported to him "newspaper accounts of small-pox occurring within 14 days' journey," or to keep "a note of small-pox occurring in no matter what part of the world." We do not know how far these matters receive attention at the Local Government Board, but they seem essentially questions which one central health authority could sufficiently study for the needs of the whole country.

LIBRARY TABLE.

Collected Papers. By the Staff of St. Mary's Hospital, Mayo Clinic, Rochester, Minnesota. For the year 1912. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 842. Price 24*s.* net.—We have on two previous occasions expressed our approval of the practice (adopted by the Mayo Clinic) of reprinting in one volume the papers published in the periodical press by the members of the staff of that hospital, so that it is unnecessary to say more than that we are pleased to see another volume of their collected papers. This volume contains some 69 papers ranging over the whole of surgery, from diffuse dilatation of the œsophagus to a bony tumour of the foot. The volume is well illustrated and well printed. It is difficult among so many interesting papers to say which are the most important, but a few may be referred to as of special interest. Three papers on Diverticula of the Bowel may be mentioned. The first is on the Diagnosis of Diverticulitis of the Large Bowel, by Dr. H. Z. Giffin. This is based on 27 cases at the Mayo Clinic on which operations were performed during the ten years ending Jan. 1st, 1912. The resemblance of the symptoms in many of the cases to carcinoma of the bowel is sufficient justification for a thorough study of this rather rare condition. The same 27 cases have been analysed in a paper by Dr. B. F. McGrath. This analysis shows that in 20 out the 27 cases the diverticula were situated in the sigmoid. A third paper is by Dr. Charles H. Mayo, and it deals with the whole subject of Diverticula of the Gastro-intestinal Tract and their Surgical Importance. All the papers give valuable data for the consideration of a subject which is now attracting a good deal of attention. Another paper to which we should like to draw attention is on the Surgical Importance of the Thymus, by Dr. C. H. Mayo and Dr. B. F. McGrath. It represents very fairly the present state of our knowledge on the subject. The conclusions that the authors draw are for the most part not very definite, except that the most satisfactory method of relieving the symptoms of enlarged thymus is by operation.

Short Key to the Identification of the Anopheline Mosquitoes of Malaya, for the Use of Medical Officers and Others. By C. STRICKLAND, M.A., B.C. Kuala Lumpur, F.M.S.: Government Printing Office. 1913. Pp. 15.—Though several large and comprehensive works exist, as well as, of course, many memoirs, in which the anopheline mosquitoes are described, it is a laborious task to hunt a particular species through many pages of description and plates or text-figures of illustration. The author of this "key," therefore, is undoubtedly performing a useful task by selecting from the total the 15 species which convey malaria, and defining them in an easy fashion. For all practical purposes, says the author, there are no more than these 15. Diagrams of wings, legs, and other parts of the mosquito organisation illustrate the characters used to differentiate one from another, the species of anopheles dealt with, and the medical officer—or indeed a less instructed person—cannot but identify by its help the flies before him. The chief danger of such a key, which is not ignored by the writer, is that the discovery or inclusion of other species may render it difficult or comparatively useless for its purpose. A list of the principal references to the literature is appended.

The Cancer Problem: a Statistical Study. By C. E. GREEN, F.R.S.E. Third edition. Edinburgh and London: William Green and Sons. 1914. Pp. 98. Price 5*s.* net.—Mr. Green's view that there is a direct relationship between the sulphur content of the fuel consumed and the mortality from cancer was considered in an annotation in THE LANCET of August 16th, 1913, p. 506, so that it is unnecessary to discuss it further here. Suffice it to say that he draws his support for his theory from the relationship he endeavours to establish between cancer incidence, occupation, and locality. The book contains illustrations of apparent malignant disease in the underground parts of plants, which the author attributes to vitriolated manures.

Practical Nursing. By the late ISLA STEWART and HERBERT E. CUFF, M.D.Lond., F.R.C.S.Eng. Fourth edition, revised and enlarged, by H. E. CUFF, assisted by W. T. GORDON PUGH, M.D., B.S.Lond. Edinburgh and London: William Blackwood and Sons. 1913. Pp. 448. Price 5*s.* net.—This work was originally published in two volumes, the first of which was reviewed in our issue of April 21st, 1900, and the second, which took some time to appear, in our issue of Oct. 17th, 1903. A further edition was reviewed in 1905, and concerning the edition now before us we can but repeat that which we then said—namely, that the book is sound, practical, and useful. The new matter deals with the treatment of disease by vaccines, light, and X rays, and the rationale of these three methods of treatment is clearly and simply explained. The book is one that might be useful to newly qualified men just entering practice

MISCELLANEOUS VOLUMES

THE South African Red Cross Society, recognising the large number of persons to which the mining industry of various kinds in South Africa gives employment, and the special liability to serious accidents, often of a specialised character, has issued an admirable little volume, entitled *First Aid in Mining*, by Dr LOUIS G IRVINE (Johannesburg South African Red Cross Society 1913 Pp 118) The booklet describes the materials provided for first aid treatment in mining accidents, the usual first-aid treatment for wounds, fractures, bleeding, &c , and the transport of the injured in mining accidents with descriptions of various kinds of stretchers for use underground These are followed by chapters on Accidents from Poisonous Gases ("gassing"), from Electricity, and Cyanide Poisoning The book will be useful in many industrial works as well as mines —— We have already noticed several of the excellent manuals published by the British Red Cross Society To these Lieutenant Colonel S GUISE MOORES, R A M C , has now added a *Hygiene and Sanitation Manual* No 4 (London, New York, Toronto, and Melbourne Cassell and Co , Limited 1914 Pp 184 Price 1s net) It has chapters on the Prevention of Disease, Water and Water supplies, Food and Sanitation, Personal Hygiene and Allied Subjects, Household Sanitation, and Field Sanitation, with appendices concerning the Red Cross and its Work There are some admirable coloured illustrations of various disease micro organisms, besides ample diagrams and sketches to illustrate sanitary construction and other matters In view of the importance attached in the modern defence scheme to the services of voluntary aid detachments a manual of this description was much needed ——The *Aids to Medicine*, by Dr BERNARD HUDSON (London Baillière, Tindall, and Cox 1914 Pp 322 Price 3s 6d net), now appears in its second edition It is claimed that the subject matter has been revised, added to and brought up to date, and such we have found to be the case by some tests which we have made Works of this character, we find it necessary to repeat, may be useful, but only if properly used as adjuncts to serious work, and not as substitutes therefor —— The Scientific Press, Limited continues to add to its Pocket Guide Series, price 1s each net In *Asepsis and How to Secure It* Mr H W CARSON, F R C S , gives such details for nurses as are calculated to enable them intelligently to coöperate with the surgeon and to impress upon them the importance of forming surgical habits In *Wounds and their Management*, Dr J K WATSON gives an intelligent summary of the view of the subject which will prove of service to nurses and to first aid students *Surgical and Medical Dressings and other Applications*, by M R HOSKING, compresses a great deal of useful information into a small space The Scientific Press also sends us the *Nursing Mirror Pocket Encyclopædia and Diary*, 1914, and the *Midwife's Pocket Encyclopædia and Diary*, 1914 (the price of each of which is 6d net) both of which contain, besides blank diary sheets, much suitable information about a wide range of professional subjects such as antitoxins, bacteria baths, diet, fumigations, legal notes, electricity, registration of births and deaths, the Midwives Act, and rules of the Midwives Board

We have had occasion to refer to many books dealing with South Africa and the South African war, and to these must now be added *Sister Henrietta* (London Longmans, Green, and Co 1914 Pp 157 Price 2s 6d net) Edited by Dowager Lady LOCH and Miss STOCKDALE — Sister Henrietta (Stockdale) was a pioneer of the nursing craft in South Africa and her organising and administrative capacity did much to build up the nursing profession in the Dominion The book deals with her home life, extracts from her correspondence and her diary during the war from October, 1899, to February, 1900—i e , during the siege of Kimberley The final chapter deals with hospital work in Kimberley from 1879, and is written by one of Sister Henrietta's oldest friends and fellow workers who came to work under her there in that year Lady Loch, in the preface, speaks of Sister Henrietta as "one of the finest women characters I have ever known in my long life," and judging from the portrait opposite the title page one can well believe it

An interesting book is *The Garden City Movement Up to Date* (London Garden Cities and Town Planning Association 1914 Pp 82, with 40 plans and 22 views Price 1s net), by Mr EWART G CULPIN The introduction reviews the history of the movement along the lines advocated by Mr Ebenezer Howard, from 1899 to 1914 The essential principles of a garden city are laid down, and the differences are defined between garden cities, garden suburbs, and garden villages In the introduction to the second edition the phenomenal growth of the system in 1913 is *detailed*, but the warning is added that "many of the schemes that are called garden city schemes have nothing in common with the Garden City Movement but the name, which they have dishonestly appropriated " Pages 19 to 60 are occupied with particulars of the various estates arranged in alphabetical order, while pages 61 to 67 deal with the garden city movement abroad A table gives a summary of the present position of all those estates and societies of which particulars are available (58 in number) as regards area, proportion developed, mode of control, houses and population, rents and rates

JOURNALS AND MAGAZINES

The Journal of Physiology Edited by J N LANGLEY, Sc D , F R S Vol XLVII No 6 Feb 27th 1914 Cambridge University Press Pp 407–508 Price 6s 6d — The Effect of Glucose on the Gaseous Metabolism of the Isolated Mammalian Heart, by C Lovatt Evans With a view to obtain data as to the influence that glucose exerts on the gaseous exchanges of the normal heart, which might subsequently be studied in the hearts of diabetic animals, the author experimented on the now well known normal heart lung preparation (dog) The addition of glucose to the circulating blood of such a preparation raises the respiratory quotient which in the author's opinion indicates that the isolated organ has the same power as has the entire organism to carry out to full completion the oxidative processes which it commences The respiratory quotient, however is not raised beyond a certain maximum, which usually lies below 0 9 The respiratory quotient of the heart is markedly increased by previous carbohydrate diet and it is then often decidedly higher (above 0 9) than that which is obtained by the addition of glucose to the blood It is calculated that the normal heart of the dog obtains about one third of its energy supply by oxidation of carbohydrate But in animals deprived of carbohydrates for some time previously the amount may be, and usually is, much less than this —Further experiments on the Action of the Vagus on the Electrogram of the Frog's Heart, by G Ralph Mines This contribution enlarges and carries forward the author's intimate study of this subject Apart altogether from the tecl [illegible]

“AMPSALVS”

THE MOST SIMPLE,
THE MOST CERTAIN,
THE MOST ECONOMICAL

Apparatus for the instantaneous preparation of an aseptic solution of NOVARSENOBENZOL (Ehrlich's 914) for its aseptic filtration and for its direct aseptic entry into the syringe.

The NOVARSENOBENZOL (Ehrlich's 914) is contained in the ampoule P, which has been hermetically sealed after having been freed from air.

Numerous tests have led us to prefer keeping 914 in a vacuum to keeping it in nitrogen. By the industrial preparation of nitrogen by means of fractional distillation of liquefied air, it is practically impossible to obtain the pure gas. It invariably contains traces of oxygen, which tend to cause a change in the 914.

The body of the flask L contains freshly doubly distilled and sterilised water. A filter tube F, sealed at its upper end, is immersed in the water to the bottom of the flask.

METHOD of EMPLOYMENT.—The ampoule P is broken at the point T, after having been incised by a file. The stilet supplied with the apparatus, having been sterilised by heat and then cooled, is now introduced into the open tube and the ampoule broken in such a manner that all the 914 falls into the distilled water. The procedure is readily carried out; the flask should now be shaken. The Novarsenobenzol dissolves very rapidly. The vertical tube is now opened at T. Into the rubber cylinder, which projects, the nozzle of a glass syringe having 10 cc. capacity is now introduced, and the fluid gently aspirated. The aseptic and filtered solution of 914 thus reaches the syringe directly (Fig. 3). A few drops of fluid remain at the bottom of the flask and in the filter tube, but we have allowed for this in the quantity of 914 provided.

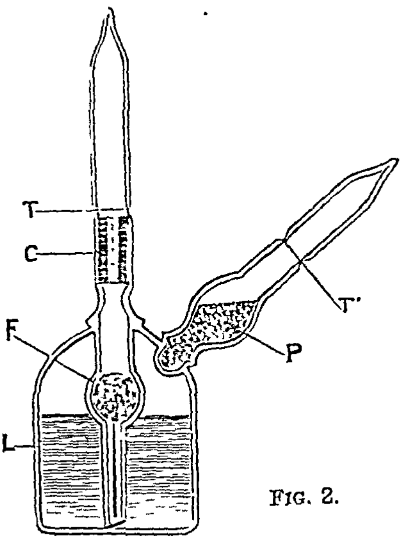

FIG. 2.

PRICES TO THE PROFESSION of our patented “Ampsalvs,” containing 914 and doubly distilled water, free from air:—

“Ampsalvs,”	containing	0·15 grm. (2 grs. 25) ...	4s. 6d.

“SUPSALVS”

Stable Suppositories containing ARSENOBENZOL (EHRLICH'S 606)

(PROFESSOR BAGROV'S METHOD.)

The rectal method of administration of 606 may be recommended to medical men who do not wish to employ intravenous injections. It yields excellent results, absolutely comparable with those obtained by the intravenous method, and is free from all risk.

This success is explained by the well-known experiment of Levaditi: “If living treponemas be placed in a solution of arseno-benzol (Ehrlich's 606), they continue to live in it. But if a trace of extract of liver be added *to the mixture* the treponemas are destroyed.”

If 606 has to be taken up and transformed *by the liver* in order to become toxic to the treponema, there can be no better mode of absorption of the drug than *by way of the intestine*, since all the *veins of the intestine* join the *portal vein*. If this be the case no route could be more indirect and more unsatisfactory for active treatment than one that is not intestinal or not intravenous (i.e., pre-hepatic), since some of the drug must necessarily become fixed everywhere before its passage through the liver has activated it.—Dr. SABOURAUD, *La Clinique*, 13-4-13.

As the result of numerous clinical experiments Dr. Bagrov of Moscow has arrived at the same conclusions, and extols the rectal method of administration of 606.

In order to render the employment of suppositories containing 606 practicable, it was necessary to find some excipient that does not alter the active principle, even if kept for a long time, and that facilitates its absorption by the intestinal mucous membrane. This requirement has been realised in our suppositories, each of which contains 0·10 grm. (1 gr. 5) of arsenobenzol (606).

Box of 6 “Supsalvs,” Adults, 12s.; do., Infants, 7s. 6d.

MODE of EMPLOYMENT.—One suppository every three days, preferably after the bowels have been cleansed by an enema, until six suppositories have been administered. Then an interval of a fortnight. The treatment is then repeated in the same manner, until three series of six suppositories each have been employed. In acute cases one suppository may be administered daily without any harm, treatment being continued for a week.

THE LANCET.

LONDON: SATURDAY, MARCH 21, 1914.

The University of London.

ALTHOUGH the proposals set forth in the Report of the Royal Commission on University Education in London may not be acceptable in all details, yet the broad general principles of this report provide a basis from which, in our opinion, a workable scheme can be evolved. The aspect on which we still attempt to concentrate the attention of our readers is whether or not the scheme proposed in the report, if adopted in its main principles, is calculated to produce a real university in London—an institution, that is, which shall not only complete the purely educational curriculum of the student, stamping him as qualified in certain professional, literary, or business directions, and moulding him by contact with his fellows, but shall also provide facilities for research and support the cause of learning by growing proportionately with the development of the world's wisdom. The question which at once becomes of supreme importance is how to deal with the external side of the present University, and how to arrange the granting of degrees to external students. There is no doubt that the chief reason for the failure of the University of London to achieve what was expected when it was reconstituted in 1898 is the existence among the students of internal and external sections whose interests are irreconcilable; while an added disability is the unworkable character of the organisation. There is danger that unless some solution of the difficulties thus caused can be found, such as will prevent their hampering influence upon the development of the best aspirations of the University, the work of Lord HALDANE'S Commission will be of no avail.

The system on which the granting of external degrees is founded is one under which, in the hands of the University of London, many great men have been educated, and it must be admitted that this system fulfils a need in the country for the present; and so long as this is the case it should, and will, continue. But it is based upon the view that the passing of an examination is the main preliminary to the taking of a degree, so that it becomes a matter of minor importance how or where the knowledge has been acquired. So long as this system holds a prominent place in the University of London, out of any belated reverence for old ideals, it is inevitable that students and the public at large will regard the granting of a degree as the most important work of the University, and will aspire to the degree rather than to the acquisition of knowledge and the training and discipline of the mind which should be regarded as by far the most important results of a university education and training. The essential attributes of a university consist, not primarily in the power of granting degrees nor in machinery for examining, but in teaching and in the expansion of the sum of human knowledge by the organisation and promotion of research. Much of the evidence which was laid before the Royal Commission was directed to this point, and on this follows the need for the modification of the external side of the University and for the creation of a local university, in which residence in London, and a training in a college or school of the university, should be required for graduation. The Commissioners are in complete agreement that external degrees should be abolished, and they have no doubt that in the broader national interest the sooner the demand for external degrees can be reduced to a point at which the degrees themselves can be discontinued without individual hardship the better it will be both for schools and teachers. We agree with their admission that it would not be possible in the present state of public opinion for the University to abandon completely the granting of degrees on the results of examinations alone, but as far as the Medical Faculty is concerned—and that is the one we are specially interested in—we cannot follow the reasoning of those who consider that a university discharges its responsibilities equally well by merely examining students as by training them. The scheme recommended in the Report of the Royal Commission is brought forward as part of a national policy intended to make all the universities in the country more accessible to the poor but capable student, and when this is carried out the Commissioners believe the demand for external degrees will dwindle and ultimately disappear. We are entirely of this view, but if the end of the external student is approaching naturally violent interference becomes unnecessary.

Here some points in the reconstruction of the University proposed by the Commissioners may be conveniently recalled. The Senate, it is suggested, should be constituted as a small body essentially lay in composition—that is to say, not composed of the teaching element so as to be in any way representative of particular interests; while there is to be withdrawn from it the present strong representation of the external side, large and important powers and duties are to be allocated to the Faculties which are to be composed of the teachers. All these things would have the effect of creating a governing body which could carry out big decisions with promptitude, and could make wise delegations of authority and responsibility in the necessary directions. Although the Commissioners recommend that candidates who have not studied in the colleges or schools of the University should be admitted to the general examinations for degrees, there are two groups of studies in which

METCHNIKOFF gives a full account of the investigations which he has been carrying on for the last four years to solve some of the bacteriological problems in connexion with epidemic diarrhœa. The conclusions at which he arrives are of interest as showing that probably two varieties of bacteria are always concerned in the pathological process, one being proteus, the other being one of a considerable number of alternative types, the reciprocal reaction of the two varieties being symbiotic in character.

The unsatisfactory interpretation of the pathogenesis of epidemic diarrhœa among infants in terms of pure bacteriology induced CZERNY and FINKELSTEIN in Germany and ROTCH in America to search for other causes, and hence have arisen in their various degrees of elaboration the several theories of "food-injuries," propounded by these observers and their followers. It is needless to explain here exactly what these theories are, how they differ, or how they agree, but generally it may be stated that it is claimed that the food of an infant, though of irreproachable cleanliness and absolutely germ-free, is yet capable, if given in excess or in unsuitable form, of producing injuries in the digestive organs or to the processes of nutrition, whose symptoms are indistinguishable from those classified as epidemic diarrhœa. The old dogma that breast-fed infants are relatively immune to the ravages of summer diarrhœa finds ample justification in this food-injury theory, for there is some physiological adaptation of the natural supply of milk to the requirements of the breast-fed infant: and further, MEINERT has shown that the demand for increased fluids in hot weather is regulated by the breast, for as the result of numerous observations he has been able to prove that breast milk is thinner and weaker in summer than in winter. Among bottle-fed infants the increased thirst in hot weather is usually met by an increased consumption of the solid as well as of the fluid constituents of milk, hence the aggravated dangers of food-injuries among the artificially fed. The experiences of carefully conducted infant consultations, both in this country and abroad, certainly seem to show that the disproportionate incidence of epidemic diarrhœa among breast-fed and bottle-fed infants is largely a matter of control, especially when accurately measured quantities of dried milk are employed in the feeding. From the theory of food-injury to the theory of heat-injury was an easy and natural progression, and at the present moment, as all medical men know, the tendency is to attach great and increasing importance to the direct effects of heat in the determination of summer diarrhœas. Among investigators on these lines SCHLOSS, SALLE, LIEFMANN, LINDEMANN, FLÜGGE, and many others, have contributed evidence to show that there is a certain parallelism between the incidence of diarrhœa and the maximum temperature, and in this connexion it is of extreme importance to note that the maximum temperature obtaining in small and badly ventilated rooms by no means synchronises with that registered in the open air. The temperature within may show a retardation of some five or six hours, and often exceeds the temperature without by some 9° or more. The high temperature of small rooms, possibly also the increased humidity of the air, and its defective circulation, must clearly be taken into account as important factors in the etiology of diarrhœa. Injuries produced by heat may be of exactly the same nature as injuries produced by food, for heat may render an otherwise physiologically adjusted dietary relatively excessive.

It seems, then, that the problem of the etiology and pathology of summer diarrhœa can be solved neither by the bacteriological theory of ESCHERICH, nor by the food-injury theory of CZERNY, nor by the heat-injury theory of FLÜGGE and MEINERT. None of these theories singly and individually are capable of explaining the rise of the incidence in summer and the relative immunity of breast-fed infants, though taken in conjunction and in combination they may be regarded as affording an adequate solution.

It was hoped to discover by the convening of this timely conference at the Queen's Hospital the best means of securing the coöperation of the public, of the local health societies, and the medical officers of health in a concerted attempt to prevent the annual sacrifice of infant lives through epidemic diarrhœa. The authorities at the hospital recognise that, beyond providing a special ward for the reception and treatment of urgent cases and special facilities for the treatment of mild cases in the casualty department, they are powerless to stem the tide of this annual visitation. The medical committee of the hospital has drawn up full directions for the guidance of the resident staff of officers, a very necessary prevision in view of the constantly changing character of its *personnel*. The medical committee has further published in leaflet form certain simple rules for the treatment and prevention of the complaint. These are clearly stated and intended for wide distribution among the residents of the neighbourhood. The hospital authorities further earnestly invite local health societies to carry on an active educational propaganda, and beg local nursing institutions to follow up the advice given at the hospital by appropriate domiciliary visits. It is quite clear, however, that if these measures are to bear fruitful results the medical officers of health in the vicinity must lend all the official machinery of their departments in support of this activity on the part of the charity.

EAST LONDON NURSING SOCIETY.—The annual meeting of this society will be held at the Mansion House on Monday, March 30th, at 3 P.M., under the chairmanship of the Lord Mayor. Among those who will speak is Sir Thomas Barlow. The object of the society is to nurse the sick-poor of East London in their own homes by means of trained resident nurses.

Annotations.

"Ne quid nimis."

REGISTRAR-GENERAL'S NEW ANNUAL SUMMARY.

WITH the issue for 1912, which appeared early in the following year, the publication of the Registrar-General's annual summary as a separate document was discontinued. Early in each successive spring the appearance of this publication is eagerly sought for by local medical officers of health, because it contains authoritative statistics which are not otherwise obtainable, but which are nevertheless indispensable for the completion of their own annual reports. In these circumstances it occurs to us that those medical officers who do not receive direct returns from Somerset House will be interested to learn that, from the current year onwards, this indispensable information will be incorporated in the return for the December quarter of each successive year. The return (No. 260) for the last quarter of 1913 is now before us, and we are glad to note that it contains, in tabular form, the precise information referred to. And this, as a supplement to the quarterly returns for the last quarter of the year, will probably be published in future at an earlier date than is practicable under existing circumstances.

THE SUPPOSED DANGERS OF RIDING ASTRIDE.

THE Kaiser has issued an order expressing his wish that the wives of German army officers shall discontinue the practice of riding astride on horseback. A medical correspondent in the *Times*, in calling attention to this, asserts that any woman who habitually rides astride endangers her health and courts disaster. He further maintains that the strain accompanying the new seat tends to displace certain vital organs, or at least to render their supports insecure, and to foster malpositions and prolapse. The main reasons which are put forward by those who advocate riding astride for women is that there is less liability of the rider being dragged if her horse falls, and that the tendency to make the horse's back sore is minimised. No doubt with the old-fashioned style of riding habit and stirrup there was a very considerable risk of the rider being dragged if her horse fell, but with the modern safety skirt and safety stirrup this danger has practically disappeared. It is usually said that a good lady rider on a side saddle is in no danger of being thrown unless her horse falls. No doubt the seat is a very safe and secure one, but it is more difficult to learn to ride well on a side saddle, and with an indifferent rider the strain on the horse is certainly greater than when he is ridden astride. The matter is obviously one upon which authorities on the subject are not altogether agreed, and there are, no doubt, two sides to the question. In our opinion, however, the medical correspondent in the *Times* exaggerates the dangers of the new mode, and his positive assertions require some qualification. At first sight it might appear that the astride position, involving as it does some separation of the thighs, would cause relaxation of the muscles of the pelvic floor and so predispose to displacements. In the case of a rider with stirrups of the ordinary length and with a proper seat, there must be an amount of pressure on the pelvic floor more than sufficient in our opinion to counteract any relaxation due to the separation of the thighs. Further than this, whenever the saddle is gripped as it instinctively is, except when the rider is, so to speak, riding at ease, the contraction of the adductor muscles of the thighs is accompanied by a contraction of the muscles of the pelvic floor. At the very time then when a displacement appears to be most likely to occur, for instance in taking a jump or restraining a restive horse, the muscles maintaining the grip upon the saddle—namely, the adductor muscles of the thighs—come into action, and their contraction is accompanied by a corresponding contraction of the muscles of the pelvic floor, and any tendency to a displacement of the pelvic organs is in this way counteracted. By "the strain accompanying the new seat," we take it the writer means the *muscular strain accompanying the grip of the* knees on the saddle, and we see no reason to think that this would produce the results he anticipates, nor could we admit that simple separation of the thighs is accompanied by any tendency to displacements. Our objections to riding astride for women, if we were asked our opinion, would be based, not upon any possible danger of injuries to the pelvic organs, but upon the view that the seat is not nearly so secure a one for the average woman rider as that on a side saddle, and because the danger of being thrown is much greater. At the same time the risk of being dragged if thrown is certainly less, although, as we have pointed out, with a properly made safety habit and stirrup even on a side saddle this risk is a very small one. Any danger of injury to the pelvic organs when riding astride must be associated with the greater insecurity of the seat and the increased risk of being thrown, and not with the position *per se*, which we do not think in the case of a healthy woman is likely to have any injurious effect upon the pelvic organs.

PROPOSAL TO ESTABLISH TRAINED NATIVE MEDICINE MEN IN NATAL.

UNDER the laws passed by the old Natal Parliament it would seem that a most pernicious practice had grown up, under which the Government licensed certain natives, who had received no medical or nursing training of any sort, to practise medicine amongst the native inhabitants of the province. These natives, it is said, for the most part belonged to an ignorant and superstitious class, and to all intents and purposes were simply licensed witch doctors. Whatever may have been the reasons that led the Natal Government to license these men they can hardly be valid to-day. The Natal Medical Council was asked by a deputation from the Natal Missionary Conference, consisting of European and native clerics, including one or two medical missionaries, to consider some feasible means by which the present state of

the approval of the members of the deputation, for they considered it necessary to concede something to the feeling of Natal natives that they should be doctored by their own people. The deputation itself favoured the licensing of natives trained on a standard lower than that of the European substance present which is essential to the assimilability of food. If we accepted the position laid down we should have to conclude that there is something radically wrong with our methods of preparing food which seemingly ought to have favoured a general distribution of "deficiency diseases." A letter in another column has prompted these remarks.

THE COMPLIMENTARY DINNER TO SURGEON-GENERAL GORGAS.

AT this dinner, which will be held on Monday next, March 23rd, at 7.45 P.M., at the Savoy Hotel, we understand that the Archbishop of Canterbury and the Lord Chancellor, Lord Haldane, will be present, as well as the Colonial Secretary, Mr. Lewis Harcourt, and Viscount Bryce. The dinner is supported by Sir Rickman Godlee, President of the Royal College of Surgeons of England; Sir Francis H. Champneys, President of the Royal Society of Medicine; Sir David Ferrier, President of the Medical Society; Dr. W. A. Hollis, President of the British Medical Association; Sir Havelock Charles, President of the Society of Tropical Medicine and Hygiene; Sir William Osler, Regius Professor of Medicine, Oxford; Sir Clifford Allbutt, Regius Professor of Medicine, Cambridge; Surgeon-General Arthur W. May, Director-General of the Naval Medical Service; Sir W. Launcelot Gubbins, Director-General of the Army Medical Service; Professor W. J. R. Simpson and Dr. F. M. Sandwith, of the London School of Tropical Medicine; Sir Ronald Ross, Sir James Reid, and Sir Frederick Treves. The chair will be taken by Sir Thomas Barlow, President of the Royal College of Physicians of London, and the organisers of the dinner are particularly anxious that representative medical men should be present to do honour to their distinguished American guest. All communications should be addressed to Mr. J. Y. W. MacAlister at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W. The dinner tickets are 25*s*., and cheques should accompany applications.

"DICHOTOMY" IN THE UNITED STATES AND IN CANADA.

THE dodge of dividing fees secretly between the general practitioner and the operating surgeon was stated publicly not long ago to be rife in the United States and Canada. The question was discussed at the time with an acrimony that, despite some weak evidence, went far to prove the custom to be in vogue; and now the matter is again on the tapis. At the twenty-third annual meeting of the Western Surgical Association held in St. Louis on Dec. 19th and 20th, 1913, Dr. Jabez N. Jackson, of Kansas City, Mo., the President, in his presidential address, took "dichotomy," as the reprehensible practice is called, for his main subject. His objections to the practice were the obvious ones, and were formulated in the obvious manner. He said that dichotomy induced family practitioners to betray the confidence of their patients who were referred to surgeons, not necessarily the most competent, not those who offered the greatest possibility of the saving of life or the preservation of health, but to men who paid coin to get hold of their victims. By this practice the patients were robbed, while it penalised honesty in those who sat idly by rather than make shameful bargains, allowing less competent competitors to buy their practices. Finally, and perhaps worst of all, it led to many unnecessary operations with their attendant risk and expense. "In all it was a betrayal of trust, encouraged dishonesty, bred incompetency, and should, in short, be regarded as a crime." The indictment is not too severe for the offence—in fact, the professional degradation of "dichotomy" can hardly have required pointing out. What is needed is a remedy—viz., the public exposure of known offenders, and this is the course that is now being widely discussed and forcibly advocated. In Canada the practice of secret division of fees was stigmatised no less harshly some two years ago at the annual meeting of the Ontario Medical Association by Dr. Herbert A. Bruce, of Toronto. Dr. Bruce appeared to admit that the custom existed by the terms of reprobation which he considered it his duty to use. Enough words have been wasted in describing the professional enormity of the offence; we should now like to see some of the offenders named and shamed. Surely if the sin is so common many of the sinners must be known.

MEDICAL PROTECTION.

THE annual report of the London and Counties Protection Society, which will be presented to the annual meeting of the members on March 25th, discloses once more a record of steady growth and of increasing usefulness. Since the last annual meeting the society has lost its President, Sir Jonathan Hutchinson, who had filled that office during the whole 22 years of the society's existence. In his place Dr. G. A. Heron has been elected, and has resigned the treasurership in consequence, to which Mr. C. M. Fegen has been elected in his stead. The report contains cases illustrative of the defence work done on behalf of the members. Interesting as many of these cases are, there is a strong similarity between the events of one year and another; and they point very strongly once more the moral which impresses itself instantaneously on all who read them—namely, the imperative necessity of an organised and coöperative system of legal defence for the medical profession. With increasing experience of the new system inaugurated in 1911 the financial position of this society is growing rapidly stronger and more assured. It will be remembered that in that year the constitution of the society was altered in such a way as to give the council power to insure members up to an amount of £2000 in any one case and up to an aggregate of £22,000 for the whole society against costs and damages given against them. Previously the society had insured members only against the actual costs of their defence. It is evident from the financial statement that the increase of the subscription from 10*s*. to £1 per annum has so far been more than adequate to cover the extra risk insured; and the consequence is that the reserve funds of the society are accumulating rapidly. This is, of course, a source of great strength, and if the favourable experience of the society in respect of this part of its work continues it will be possible either to reduce the subscription which the members pay or to terminate the arrangement whereby the society reinsures with Lloyd's the whole of its annual risk of adverse verdicts beyond the first £2000, thus saving the annual premiums paid to cover this contingency. As previously, the society was able to recover a substantial proportion (nearly £900 out of £2300) of its law costs from defeated adversaries. The whole of the accounts and balance-sheets reveal a promising condition.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE annual Congress of the Ophthalmological Society of the United Kingdom will be held, under the presidency of Mr. F. Richardson Cross, on Thursday, Friday, and Saturday, April 23rd, 24th, and 25th. The meetings will take place at the rooms of the Royal Society of Medicine, 1, Wimpole-street. On Thursday and Saturday mornings papers will be read from 10 A.M. till 1 P.M.; on Friday morning there will be a discussion, to be opened by Mr. E. Treacher Collins and Lieutenant-Colonel H. Herbert, on Post-operative Complications of Cataract Extraction. The annual business meeting will be held at 4 P.M. on Thursday, and at 5 P.M. on the same day Professor Uhthoff, of Breslau, will deliver the Bowman lecture on Experiences and Considerations on the Importance of Ophthalmology in Brain Surgery. Members of the society and their friends will dine together on Thursday evening. It has been arranged to hold a clinical meeting on Friday afternoon at the Central London Ophthalmic Hospital, Judd-street, W.C. During the congress a museum of objects of ophthalmic interest will be exhibited in the Bowman library at the Royal Society of Medicine. Communications respecting the scientific meetings should be addressed to Mr. G. Coats, 50, Queen Anne-street, W., respecting the museum to Mr. M. S. Mayou, 30, Cavendish-square, W., and respecting the dinner to Mr. Elmore Brewerton, 84, Wimpole-street, W.

NAVAL AND MILITARY MEDICINE AT THE ANTIPODES.

THE British public are not likely to forget the patriotism so vigorously demonstrated by our Colonial kinsmen during the war in South Africa, and it is not too much to say that our home military authorities found a good deal to learn from the capable and energetic methods of administration of the daughter States. In Australasia military training is now compulsory on all male citizens; from the age of 12 to 18 in cadet corps, and from 20 to 26 as citizen soldiers; in New Zealand the liability ceases at 25. Colonel James R. Purdy, Director of Medical Services, New Zealand, makes some very pertinent observations in a book which he has just published and in which an address delivered by him at the Australasian Medical Congress of 1911 is reproduced. Colonel Purdy urges that only the very best youth of the country should be taken for the army. There is no sense in training up a soldier to fight, and when the day of battle comes finding he is unable for physical reasons to do so. He has satisfied himself that only men of the very highest stamp of physical development can possibly stand the stress of modern methods of warfare; he considers that 40 per cent. of the youth of Australasia are for some cause or other unfit for efficient military service, but believes that in a few years, owing to the great improvement in physique effected by physical training, this percentage of unfitness will be very greatly reduced. He insists on the need for all-round military training for the army medical officer. For the actual treatment of sick and wounded in war civilian practitioners can always be obtained in large numbers, but for the administrative duties of the medical service long and varied training is necessary. Everyone knows and acknowledges the importance and the difficulties of the supply department in war; but it has only recently been realised that it is as difficult a problem to get a wounded man down to the base as to get a dead bullock up to the front. In war time it is not the performance of brilliant surgical operations, nor the successful treatment of serious diseases, that constitutes the chief value of the medical department; this depends on the prevention of disease, the rapid evacuation of sick and wounded, and the immediate treatment of minor ailments and injuries, so as to get the men back to the fighting line as quickly as possible. All this requires careful organisation, and Colonel Purdy mentions that New South Wales was the first country in the world to possess a properly organised, properly equipped medical force that was the admiration of all who saw it working in South Africa. In another paper Colonel Purdy, speaking from his experience in the South African war as to water supply in the field, states his firm opinion that the best and most rational system is to encourage every man to boil water for himself. If made into tea, as was done by the Australians in the war, the practice is both effectual and popular.

OCEANOGRAPHY AND PUBLIC HEALTH.

DURING some extensive ceanographic investigations, conducted mainly wi the object of localising distant icebergs by obser tions upon the electroconductivity of sea wate Dr. Myer Coplans, of Leeds University, happen by chance upon certain facts which may have an portant bearing on the health of passengers on lantic liners. By means of a compensated cond ivity salinometer of his own invention Dr. Copl s estimates the electric conductivity of the wate .8 feet below the surface, and is thus enabled t educe the degree of its salinity. Whether thi method will provide an infallible indication of e neighbourhood of icebergs is not yet proved; if it does, the travelling public will have much to thank Dr. Coplans for. While measuring the electro-conductivity of the water in the Gulf of St. Lawrence he found that near the mouth of each tributary river there is a rise in the salinity of the water. The water of Lake St. Peter and above was much more pregnant with saline products than that of the tributaries below Three Rivers and Quebec. This result he ascribes to the fact that the sewage from Ottawa and Montreal is largely deposited in the broad expanse of Lake St. Peter. The importance of this resides in the fact that the ocean-going steamships plying to and from Montreal take their fresh water from this place. If Dr. Coplans's contention that this water is in reality heavily contaminated with sewage is correct it is obviously a matter of the greatest importance that ship-owners should know this and act upon it. It is to be hoped that the authorities will take steps to ascertain whether this water is or is not bacterially infected, and that meanwhile it will be treated as under some suspicion. That this question of public health should arise out of researches undertaken for the detection of invisible icebergs at sea is only another instance of the unexpected gifts with which science proverbially rewards now and then her patient followers. The significance of these observations in the St. Lawrence circuits, the relative position of the essential parts at the moment of "break" will be easily understood. Below the jets are just leaving the primary contacts P P, and above the connector C is coming into line with the segments S S, allowing the secondary current to flow through the tube with practically no resistance. The scheme may be described, in other words, as a combined interrupter for the primary and secondary circuits, so set that as one circuit is closed the other is open.

The simplicity and efficiency of the device will be apparent to anyone acquainted with X ray apparatus, and the wonder is that it has not been put into use before. The scheme is similar in principle to the mica valve of Mr. Leslie Miller, but in this case the wide air-gap is preferable as a resistance to the mica disc, and it admits of more complete closure of the circuit at the moment of "break." My device has been patented for the benefit of Messrs. Newton and Wright, who have borne all the trouble and expense of developing the idea in practical form.[1]

The apparatus is mounted in a closed cabinet with the coil on top and the break and its attachments inside. Needless to say, any coil can be fitted by merely adapting the supports upon which it rests. The controls for the break are placed on one end of the cabinet, and a switch table of the simplest form attached by a flexible cable regulates the output of the coil. I believe the apparatus is one that will become popular among radiologists for such work as comes within the range of a coil and mercury break. It adds very little to the original cost of the X ray outfit, and this is very soon compensated for in the elimination of expense for valve tubes, and the longer life and steadier working of the X ray tubes. The greatest advantage is that results are more uniformly good in every way.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on March 12th, Sir RICKMAN GODLEE, the President, being in the chair.

A letter was read from Mr. Jonathan Hutchinson resigning his seat on the Council on account of pressure of hospital work.

The PRESIDENT stated that the vacancy thus occasioned would be filled at the annual meeting of Fellows in July.

A report was read from Mr. C. H. Golding-Bird on the proceedings of the Central Midwives Board during the past year. The best thanks of the Council were given to Mr. Golding-Bird for his services as the representative of the College on that Board, and he was re-elected for another year.

Sir Henry Morris was re-elected for one year as the representative of the College on the General Medical Council.

A letter was read from Mr. D'Arcy Power reporting his attendance before the Royal Commission on Venereal Diseases to give evidence as requested by the Council.

Fixity of Tenure of Medical Officers of Health.

The PRESIDENT stated that in accordance with the wish of the Council expressed at their last meeting he and the Vice-Presidents had received at the College some medical officers of health and had conferred with them on the subject of fixity of tenure. It was resolved to send the following letter to the President of the Local Government Board:—

"The attention of the Council of the Royal College of Surgeons has been directed to the desire of the medical officers of health under the Local Government Board to secure *fixity of tenure* and some definite system of *superannuation and pensions*, and they have been asked to support the endeavour which is now being made to bring this matter under the consideration of His Majesty's Government.

The Council are aware that this is no new question, and that it may be considered from more than one point of view. They have endeavoured to make themselves acquainted with the arguments put forward on both sides, and the facts as far as they have been able to ascertain them.

Though feeling a special interest in the diplomates of the College, the Council recognise that if the request cannot be supported on public grounds it is not worthy of consideration. It is to this point of view, therefore, that they have exclusively directed their attention.

It appears to the Council that there must be something wrong with a system under which the guardians of the public health hold appointments terminable at short notice under those whose interests are likely to be interfered with by the exposure of unsanitary conditions, or the suggestion of sanitary improvement. Yet this is what the present system in many districts involves. The Council have been impressed by the confession of men occupying important positions, that they are conscious of being influenced in the discharge of their duties by the fear of losing their appointments.

Moreover, it is often stated that the medical profession is becoming more and more alive to the unattractiveness of public health appointments, even those commanding good salaries where the tenure is insecure and there is no system of superannuation. It appears likely, therefore, that the quality of the applicants for them will deteriorate.

Considering the vital importance of the matter at stake the Council, whilst fully recognising the weight of the arguments adduced against the proposed change, which they have endeavoured to consider impartially, cannot think that they are strong enough to outweigh those in favour of the request of the medical officers of health.

The Council, therefore, feel that it would be for the advantage of the community if security of tenure with a corresponding system of superannuation were granted to medical officers of health under the Local Government Board, and they venture to express the hope that it may be possible for His Majesty's Ministers to give favourable consideration to the representations which are now being made to them on these questions."

The diploma of Member was conferred upon the following two gentlemen who have passed the requisite examinations and have now complied with the by-laws of the College: John Harold Cascaden, M.D. Toronto, Toronto University and London Hospital; and Thomas Trench Thompson, M.B., B.S. New Zealand, Otago University.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the twenty-second meeting of the Royal Commission on Venereal Diseases evidence was given by Mr. D'Arcy Power, surgeon and lecturer on surgery at St. Bartholomew's Hospital, and one of the representatives before the Commission of the Royal College of Surgeons and the Royal Society of Medicine.

Mr. D'Arcy Power said that from the surgeon's point of view he looked upon gonorrhœa as the more serious disease for the individual and syphilis for the race. In general surgery the effects of gonorrhœa were far-reaching, and it was an error to teach that it was a local and curable disease. Syphilis seemed to Mr. Power to be even more dangerous to the State than to the individual. The expectation of life was materially shortened for a person who had been infected with syphilis; the immediate danger extended to the second generation, and the vitality of the stock seemed diminished for several generations. Syphilis gave surgery a large amount of work. It predisposed, Mr. Power thought, to cancer and tubercle. The particular danger of the disease lay in the fact that the subsequent effects bore no necessary relation to the severity of the initial lesions.

Mr. Power thought that a *diminution* in the incidence of syphilis would best be brought about by better instruction of the medical student, and that each general hospital ought to establish a special department under the control of the senior medical officer. The department should be chiefly an out-patients' clinic and should be held in the afternoon or in the evening. A few beds might be provided, but the essence of successful treatment in syphilis was early diagnosis and prolonged attendance. The department should be thoroughly equipped with a sufficient staff of pathologists and with the necessary remedies. The expense would no doubt be considerable, but Mr. Power thought that the State would be more than repaid. He believed that the establishment and use of such departments would gradually educate the public to appreciate the danger and thereby diminish the risk. Mr. Power did not think that any organised attempt to educate the public with regard to venereal diseases was desirable; he would rather trust to the gradual growth of education through the medical profession Mr. Power was not in favour of notification of venereal diseases, at any rate not for the present.

---

[1] The apparatus is being demonstrated this evening (Friday, March 20th) at the Electrotherapeutic Section of the Royal Society of Medicine.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8620 births and 5338 deaths were registered during the week ended Saturday, March 14th. The annual rate of mortality in these towns, which had been 15 0, 15·1, and 15 8 per 1000 in the three preceding weeks, declined to 15 4 per 1000 in the week under notice. During the ten weeks of [illegible] death rate in these town [illegible] in London during the sa [illegible] the death rate last wee [illegible] 6·3 in Ilford, 7 4 in Leyton, 8 2 in Hornsey, and 8 4 in Eastbourne, to 21 4 in Reading, 22 0 in Stockton on-Tees, 22 1 in Oldham, 22 7 in Swansea, and 22 9 in South Shields

The 5338 deaths from all causes were 159 fewer than the [illegible] hich were [illegible] numbers [illegible] Of these [illegible] 113 from [illegible] om diph- [illegible] fever, but not one from small pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1 2 per 1000 in each of the two preceding weeks. The deaths attributed [illegible] 115, and 134 [illegible] o 143 last week, [illegible] f 2 1 in Oldham, [illegible] eaths referred to [illegible] 8 in the three [illegible] highest death [illegible] sbrough, 1 7 in [illegible] ey and in Cardiff, [illegible] fatal cases of [illegible] r 2 years), which [illegible] ling weeks, rose [illegible] registered in [illegible] Middlesbrough, [illegible] n Cardiff. The [illegible] had been 52, 72, and 60 in the three preceding weeks, rose to 67 last week, and included 15 in London and its suburban districts, 6 in Birmingham, 4 in Portsmouth, and 4 in Manchester. The deaths referred to scarlet fever, which had been 33, 34, and 34 in the three preceding weeks, were 31 last week, of which 6 occurred in Birmingham, 5 in Manchester, and 4 in Middlesbrough. The fatal cases of enteric fever, which had been 17, 8, and 20 in the three preceding weeks, declined to 13 last week, and included 2 in Liverpool, 2 in Salford, and 2 in Sheffield.

The number of scarlet fever patients under treatment in the London Fever and the Metropolitan Asylums Hospitals, which had steadily decreased from 3599 to 3307 in the six preceding weeks, had further declined to 3222 on Saturday last; 320 new cases were admitted during the week, against 351, 401, and 340 in the three preceding weeks These hospitals also contained on Saturday last 1318 cases of diphtheria, 339 of whooping-cough, 127 of measles, 80 of enteric fever, and 1 of small-pox. The 1240 deaths from all causes in London were 109 fewer than the number in the previous week, and were equal to an annual death-rate of 14 3 per 1000. The deaths referred to diseases of the respiratory system, which had been 245, 213, [illegible] to 223 last [illegible]

Of the 5338 deaths from all causes in the 97 towns, 188 were attributed to different forms of violence, and 390 were the subject of coroners' inquests. The causes of 36, or 0 7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, and in 73 other smaller towns. Of the 36 uncertified causes of death, 8 were registered in Birmingham, 8 in Liverpool, 3 in London, and 3 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In [illegible] tion [illegible] 1216 [illegible] week [illegible] mortality in these towns, which had been 16 5, 17 5, and 16 6 per 1000 in the three preceding weeks, rose to 17 9 per 1000 in the week under notice. During the ten weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16 5, or 1 9 per 1000 above the corresponding rate in the 97 large English towns Among the several towns the death rate last week ranged from 6 8 in Hamilton, 9 4 in Falkirk, and 14 2 in Ayr, to 20 0 in Perth, 20 1 in Greenock, and 22 8 in Kirkcaldy.

The 787 deaths from all causes were 59 in excess of the number in the previous week, and included 77 which were referred to the principal epidemic diseases, against 98 and 73 in the two preceding weeks Of these 77 deaths, 34 resulted from measles, 14 from diphtheria, 10 from infantile diarrhœal diseases, 8 from scarlet fever, 8 from whooping cough, and 3 from enteric fever, but not one from small-pox The mean annual death rate from these diseases last week was equal to 1·8, against 1 3 per 1000 in the 97 large English towns The deaths attributed to measles, which had been 42, 48, and 36 in the three preceding weeks, were 34 last week; of this number, 24 occurred in Glasgow, 4 in Edinburgh, 2 in Paisley, and 2 in Leith. The deaths referred to diphtheria, which had been 14, 11, and 5 in the three preceding weeks, rose to 14 last week, and included 5 in Aberdeen, 3 in [illegible] ases of diarrhœa [illegible] which had been [illegible] s, declined to 10 last week, of which 3 were recorded in Dundee and 2 in Glasgow. The deaths attributed to scarlet fever, which had been 6, 13, and 7 in the three preceding weeks, were 8 last week, and included 4 belonging to Glasgow. The 8 deaths [illegible] were slightly in excess of the [illegible] the quarter, and were all [illegible] ital cases of enteric fever, [illegible] Edinburgh; a fatal case of [illegible] of the respiratory system, which had been 143, 116, and 126 in three preceding weeks, further rose to 137 in the week under notice; 24 deaths resulted from different forms of violence, against 15 and 32 in the two preceding weeks.

VITAL STATISTICS OF LONDON DURING 1913

IN the accompanying table statistics of sickness and mortality in the C [illegible] politan boroughs a [illegible] regard to the notifie [illegible] that the number of [illegible] or other of the ten [illegible] to an annual rate of [illegible] at 4,518,191 persons [illegible] preceding years the rates had been 6 6, 4 5, and 5 1 per 1000 respectively. Among the various boroughs the rates last year ranged from 4 4 in the City of Westminster, 4 4 in Hampstead, 4 8 in Stoke Newington and in Holborn, and 4 9 in Chelsea, to 8 2 in Poplar and in Battersea, 9 1 in Bermondsey, 9 2 in Woolwich, and 10 1 in Deptford. The prevalence of scarlet fever showed a large increase as compared with that in other recent years, 17,552 cases being [illegible] ear, against [illegible]

Deputy Assistant Director of Medical Services (*Mobilisation Branch*) to the *Fifth Mhow Division*. Captain J. E. H. Gatt has been granted leave of absence home from India for one year on medical certificate. Captain N. D. Walker has joined for duty at Quetta Cantonment.

Lieutenant R. Davidson has embarked for India. Lieutenant J. M. Elliott has taken up duty at the Station Hospital, Rawal Pindi Cantonment. Lieutenant E. G. H. Cowen has been transferred from Lucknow Cantonment to Agra. Lieutenant L. T. Poole has joined at York. Lieutenant I. R. Hudleston has embarked for a tour of service in Jamaica. Lieutenant J. E. Hepper has been transferred from the Military Flying School at Upavon, Salisbury Plain, to Oxford. Lieutenant A. G. Biggam has relinquished duty at York. Lieutenant H. C. Todd has been transferred from Bangalore to Secunderabad.

Indian Medical Service.

Surgeon-General A. M. Crofts, C.I.E., Deputy Director of Medical Services to the Second (Rawal Pindi) Division of the Northern Army, has been granted general leave of absence for three months and ten days. Colonel R. Bradley Roe has taken up duty as officiating Assistant Director of Medical Services at Lahore.

Lieutenant-Colonel C. H. Bowle Evans has arrived home on leave of absence from India. Lieutenant-Colonel H. Pilgrim has been granted an extension of service. Lieutenant-Colonel J. L. Jones has joined at Bombay. Lieutenant-Colonel S. H. Henderson has been granted an extension of leave of absence home from India. Lieutenant-Colonel A. W. T. Buist has taken over civil medical charge at Campbellpore. Lieutenant-Colonel G. F. W. Ewens has been appointed Superintendent of the Punjab Lunatic Asylum at Lahore.

Major H. Innes, civil surgeon, Khasi and Jaintia Hill District, has been granted combined leave of absence home from India for one year. Major W. D. A. Keys has embarked for India. Major C. F. Marr has been selected as Medical Storekeeper to Government at Lahore, vice Major W. G. Richards, who has taken up duty at Madras.

Captain K. K. Mukerji has been selected for appointment as officiating Deputy Sanitary Commissioner, Burdwan Circle, Bengal. Captain R. F. Steel has been selected for permanent employment under the Government of Bombay. The services of Captain C. Holroyd have been placed at the disposal of the Government of Bengal as Superintendent of the Central Prison at Bareilly. Captain R. H. Bott has been selected for appointment as officiating Professor of Surgery at the Government Medical College, Lahore, *pro. tem.* Captain F. G. Stiles Webb has joined the North-West Frontier Province. The services of Captain M. S. Irani have been placed permanently at the disposal of the Government of Bombay. Captain N. T. Wells has handed over charge as Deputy Sanitary Commissioner of the Punjab on relief by Major E. L. Perry. Captain E. C. Hodgson has been appointed on special duty in connexion with the prevention of malaria at Madras. Captain J. D. Jones has taken up permanent duty under the Government of Bombay. Captain A. W. Greig has taken over charge as Superintendent at the Central Jail, Montgomery. Captain T. W. Harley has been appointed Superintendent of the Jail at Madura, Madras.

Special Reserve of Officers.

Royal Army Medical Corps.

Lieutenant George H. Stevenson to be Captain (dated March 1st, 1914).

Cadet Colour-Sergeant Evan Davies, from the Birmingham University Contingent, Officers Training Corps, to be Lieutenant, on probation (dated Feb. 19th, 1914).

Territorial Force.

Royal Army Medical Corps.

Notts and Derby Mounted Brigade Field Ambulance, Royal Army Medical Corps: Captain Alexander R. Tweedie to be Major (dated March 14th, 1914).

Yorkshire Mounted Brigade Field Ambulance, Royal Army Medical Corps: John Downie to be Lieutenant (dated Jan. 24th, 1914). Lieutenant Thomas E. Lister resigns his commission (dated March 14th, 1914). Edward Douglas Ellis to be Lieutenant (dated March 14th, 1914).

5th London Field Ambulance, Royal Army Medical Corps: William Bertram Hill to be Lieutenant (dated Feb. 17th, 1914).

2nd Lowland Field Ambulance, Royal Army Medical Corps: William Hislop Manson to be Lieutenant (dated Feb. 17th, 1914).

Northumbrian Clearing Hospital, Royal Army Medical Corps: Captain William Thomas Harkness, from the 1st Northumbrian Field Ambulance, Royal Army Medical Corps, to be Captain (dated March 14th, 1914).

Attached to Units other than Medical Units.—Captain Charles R. Browne to be Major (dated Jan. 5th, 1914).

For Attachment to Units other than Medical Units.—Kenneth Douglas Wilkinson (late Cadet Sergeant, Birmingham University Contingent, Senior Division, Officers Training Corps) to be Lieutenant (dated Jan. 23rd, 1914). James Anderson to be Lieutenant (dated Jan. 31st, 1914). Lieutenant Cecil William Rowntree, from the 3rd London (City of London) Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Feb. 18th, 1914).

Colonial Medical Services.

West African Medical Staff.—Mr. A. Hipwell, medical officer (Nigeria), and Dr. F. G. Thompson, medical officer (Gold Coast), have resigned. Dr. G. C. Walker, sanitary officer (Gold Coast), has retired on pension. The following gentlemen have been selected for appointment to the staff: Dr. W. H. Kauntze (Nigeria), Dr. A. R. Paterson (Nigeria), Dr. R. G. Ball (Gold Coast), Dr. E. J. H. Garstin (Nigeria), Dr. P. A. Clearkin (Sierra Leone), Dr. J. Mc.C. Clark (Sierra Leone), and Dr. J. Atkinson (Gold Coast).

Other Colonies and Protectorates.—Mr. J. T. Duncan has been selected for appointment as a Medical Officer in the Straits Settlements; Dr. G. V. Fiddian has been selected for appointment as an Assistant Medical Officer in British Guiana; Dr. J. M. Mackinnon has been selected for appointment as a Temporary Medical Officer in the East Africa Protectorate; Mr. B. C. N. O'Reilly and Mr. E. E. Wilbe have been selected for appointment as Medical Officers in the Gilbert and Ellice Islands; Dr. S. D. Stewart has been selected for appointment as a Supernumerary Medical Officer, Trinidad; Dr. G. H. Lewis and Dr. C. W. L. Cassel have been selected for appointment as Assistant Medical Officers, British Honduras; and Mr. H. B. Dodds has been selected for appointment as a Medical Officer in the Straits Settlements.

Journal of the Royal Army Medical Corps.

Among the contents of this journal for March is a joint contribution by Lieutenant-Colonel T. W. Gibbard and Major L. W. Harrison on the Treatment of Syphilis with Salvarsan, a paper read at the International Medical Congress, 1913. From the standpoint of the treatment of syphilis in the Army the authors believe that the best results will be obtained by a course of three salvarsan and ten mercurial injections prolonged over nine or ten weeks, and that the routine use of the treatment is likely to effect an annual saving of 70,000 to 80,000 hospital days. The remedy, however, must be entrusted only to those who are thoroughly acquainted with its indications and contra indications and the technique of its administration. Colonel C. Birt discusses the best method of staining treponema pallidum. In an article on the wounding effects of the Turkish sharp-pointed bullet Major E. T. F. Birrell shows that the experiences of the Balkan war, 1912-13, do not altogether bear out the general impression that the wounding power of the sharp-pointed bullet is of greater severity than that of the ogival-tipped bullet. Polar exploration is a topic of much interest at the present moment, and the report of a lecture by Surgeon E. L. Atkinson, who, it will be remembered, was a member of the British Antarctic Expedition, 1910-13, on Antarctic Experiences will be read with much pleasure by those who had not the privilege of hearing the experiences at first hand. The lecturer deals with snow-blindness and its prevention, frost bite, the hygiene of the hut, the health of the explorers, and with sledging and its effects. An article on Solutions, by Colonel R. H. Firth, supplements a previous article by the same writer on Colloids.

The Glamorgan Red Cross Gazette.

The second issue of this excellent little publication, which is to be published three times a year, is dated February, 1914, and contains among other interesting matter the second part of Major R. J. Simons's (R.A.M.C., T.F.) article on Wounds and How they Heal. The use of the second personal pronoun when an impersonal statement is intended is an unfortunate mistake likely to cause an argument to appear personal, but a writer in the *Gazette* gives an instance where the second person has been substituted for the first with ludicrous effect. An examiner asked a young lady what she would do for a bad cold in the head. The examinee replied: "I would put my feet in a bath of hot water and mustard and keep them there until you (!) were in a profuse perspiration." The *Gazette* is published by E. J. Llewellin, Cadoxton-Barry, Cardiff. Price 6*d*. a year.

Medical Governors of Gambia.

Mr. W. Telfer Campbell, colonial secretary, the Gambia, writes to the *Times* asking the relatives or others of certain governors and administrators of the colony of Gambia for portraits of these officials as a gift or on loan for copying in order that the collection of portraits of ex-officials in the council chamber at Bathurst may be completed. Among the desired portraits are those of Surgeon-Major Samuel Row, C.M.G., and Brigade-Surgeon Valesius S. Gouldsbury, C.M.G. Communications should be made to Mr. Campbell, care of the Crown Agents, Whitehall Gardens, London, S.W.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

SHEFFIELD.

Post-graduate Course on Syphilis.

DURING this winter the number of men taking out the general clinical post-graduate course has far exceeded that of any previous year, and indicates the desirability of increasing their opportunities for such work. The Faculty of Medicine has therefore decided to give a short course on the etiology, pathology, and treatment of syphilis during April and May. It will consist of about ten lectures, given twice weekly, and will include demonstrations and practical classes. It is intended to deal chiefly with recent work on the spirochæta, Wassermann's reaction, and treatment by salvarsan.

Evening Clinics for Venereal Diseases.

The Royal Infirmary has very wisely taken up the question of offering special facilities for the treatment of venereal diseases. For this purpose an evening out-patient clinic for venereal diseases has been started by members of the staff, and promises to supply a long-felt want. The attendances have proved distinctly encouraging. The board and staff of the Royal Infirmary are to be congratulated on their enterprise and initiative in this important matter, which should be widely imitated in other places. The clinic is at present limited to male patients, who are admitted without any recommendation.

Appeal for Radium.

Following a letter to the local press a few weeks ago, signed by representatives of the staffs of all the voluntary hospitals in the city, a circular appeal has been issued by a committee of the staffs, of which Professor Sinclair White, senior surgeon to the Royal Infirmary, is chairman, for £10,000 to purchase radium. The appeal has already met with considerable success, more than half the sum having been promised. There is no doubt that within a short time the rest of the amount asked for will be forthcoming.

Edgar Allen Institute.

Coinciding with the appeal for radium, the Edgar Allen Institute, to which reference was made in your columns last week, has issued an appeal for subscriptions to enable it to continue its work in medico-mechanical treatment. The generous founder, Mr. Edgar Allen, has not only equipped it, but has been responsible for its upkeep for the last three years. He now feels that it has justified its foundation, and that he should receive some assistance from his fellow citizens in maintaining it. The response to the appeal is making satisfactory progress and already more than half the required amount has been promised. There is no doubt that Sheffield is fortunate in having such an addition to its means for hastening recovery in convalescent patients, and it would be a misfortune were it to be allowed to decline or even close for lack of support. A suggestion has been made that this institute should become the place where the radium is kept. From its accessible position and the constitution of its governing body, representative of the leading citizens and of the medical profession and hospitals generally, it corresponds exactly with the requirements of a radium institute. It is to be hoped that some arrangement of this kind may be come to so as to save the cost of running two institutes in the city—the upkeep of both of which would eventually fall on the generously disposed citizens.

The Pathological Section of the Medico-Chirurgical Society.

At a recent meeting of the Pathological Section of the Medico-Chirurgical Society Dr. F. W. Mott, F.R.S., gave an interesting address on Parenchymatous Syphilis before a large and appreciative audience. This is the first occasion upon which the recently formed Section of Pathology has entertained a distinguished visitor, and the innovation proved so successful that it is to be hoped it may be made an annual event. The Pathological Section of the Medico-Chirurgical Society has so thoroughly justified its existence that a movement is now on foot to form a Clinical Section on somewhat similar lines.

Hospital for Sick Children.

A vacancy on the honorary staff of the Children's Hospital caused by the resignation of Dr. E. W. Adams, has resulted in the election of Dr. John Stokes. Dr. Adams, who is leaving Sheffield to take up his new duties as a medical inspector under the National Insurance Act, has also resigned the post of lecturer on pharmacology and therapeutics at the University. His many friends will wish him every success in his new career.

March 17th.

BIRMINGHAM.

Birmingham General Dispensary.

THE 120th annual report states that the total ordinary receipts were £10,135 18*s.* 7*d.* and the special receipts £12,564. There was a decrease in the amount received for subscriptions and supernumerary notes of £1275. The expenditure increased by £221. The total number of patients admitted during the year by ticket was 49,365, a decrease of 13,155. The average cost per patient has been 4*s.* 9½*d.*, an increase of 1*s.* 1*d.*, an increase partly due to the tuberculosis department. The number of new patients in the tuberculosis department was 760, which does not include contacts examined and found not to be tuberculous. Of the total only 113 were insured under the Act. The attendances of patients during the year had totalled 21,329, being an average of 70 per working day.

Hospital Saturday Fund.

The annual meeting was presided over recently by the Lord Mayor. Since the inauguration of the Fund in 1873 over half a million pounds have been collected. In proposing the adoption of the report the Lord Mayor made interesting comparisons with similar funds in other cities. In spite of the Insurance Act a new record has been established for the Birmingham Fund, as for the first time over £23,000 has been collected. In London the collection amounted to £50,419, and there had been a drop of £4658; at Manchester in 1912 there was a decrease of £382 and a further drop last year. At Liverpool in 1912 they lost £2132, but last year there was a fall of only £1. At Leeds in 1912 they went back £836, and last year £206. Leicester reported an increase of £498 to a total of £15,632. His lordship called attention to the fact that there were 500 firms who were not subscribing to the Fund. Of these, about half fell out over the Insurance Act, but some of these were returning. The organisation was being worked very cheaply. The report showed that the percentage on collection was 5·86*d*. There, again, Birmingham was beaten by Leicester, whose percentage was 4¼*d*. The figures for the other big towns were: London, 9½*d*. per cent.; Manchester, 11½*d*. per cent.; Liverpool, 9½*d*. per cent.; and Leeds, 6½*d*. per cent.

After-care of Tuberculous Subjects.

At a conference held between representatives of the health committee of the city council, the board of guardians, the Insurance Committees, and the City Aid Society to consider the difficulty of dealing with phthisical cases, it was resolved that the City Aid Society be asked to form a special committee for the purpose of coordinating action by the various authorities and societies. A circular letter has been sent to all institutions, hospitals, and organisations which deal with consumptives, and to all medical men in the city, inviting them to send on a form particulars of any case which comes to their notice and requires additional help. It is hoped in this way to obtain fairly complete information as to the number of such cases and the amount and kind of additional help specially needed.

The United Kingdom Police Surgeons' Association.

The annual meeting of this association was held in the Medical Institute, Birmingham, on March 14th, the President, Professor J. T. J. Morrison, in the chair. The council in the annual report, and in repetition of a previously expressed opinion, stated that the value of the association lay in the possibility so afforded for ascertaining corporate needs and taking combined action thereon. The good offices of the British Medical Association in helping to advance the inadequate scale of capitation payments in several districts were cordially acknowledged, while it was noted that a knowledge of "first aid" is now generally regarded as part of the equipment of the police force, and members were advised to bring to the notice of local authorities the practice of paying police surgeons for the necessary instruction in ambulance work. The report having been received and adopted, the following officers were elected for the ensuing year:—President: Professor J. T. J. Morrison, Birmingham. Vice-Presidents: Sir Henry Littlejohn, Edinburgh; Dr. H. W. Oulton, Dublin; Mr. F. W. Lowndes, Liverpool; and Mr. H. Nelson Hardy, London. Treasurer: Mr. J. Paul Bush, Bristol. Honorary Secretaries: Dr. Hugh F. Powell, Cheltenham; Dr. W. Hartley Bunting, Birmingham. Council: Dr. H. Barnes, Carlisle; Dr. J. F. Craig, Birmingham; Mr. G. H. Heald, Leeds; Mr. W. J. Heslop, Manchester; Dr. T. F. Higgs, Dudley; Dr. C. E. Hoar, Maidstone; Dr. L. Maybury, Portsmouth; Dr. H. B. W. Plummer, West Bromwich; Mr. W. Powell, Cheltenham; Mr. W. M. Roocroft, Wigan; Mr. W. Roughton, London; and Dr. J. Young, Bristol.

March 17th.

BRISTOL AND WESTERN COUNTIES.

Bristol General Hospital: Workmen's Subscriptions.

A FURTHER step in the campaign described in the issue of Feb. 28th (p. 638), by which a committee claiming to represent the working men of Bristol seeks to gain a footing in the governing bodies of the Bristol hospitals, was completed this week at the annual meeting of the General Hospital, when Mr. Herbert M. Baker, chairman of the committee, made a very interesting statement. Beginning by an acceptance of the claim of the working classes to be represented on the hospital committee—a claim based on their generous subscriptions—he pointed out that about 12½ per cen of the hospital expenses were met by those subscriptions. The hospital committee had for som time past been considering the advisability o establishing direct representation of the workin men, but had been hindered by difficulties in connexion with the fixing of a franchise. They had however, invited 21 firms whose employee (numbering 22,000) subscribed £20 and upwards t the hospital to send representatives, chosen by th workpeople, to meet them. These representative had constituted themselves into a standin advisory committee and had elected one of thei number to act as their representative on the hospital committee. By this means the hospital ha secured for the working man a method of direc representation on the committee, while a the same time avoiding concessions to the sel appointed "representatives" of labour. Th annual report of the charity was read, and contained many interesting items, of which the ne pathological department, the change in th presidency and in the secretaryship, and matter relating to the new wing, have already been full mentioned in these columns. The committee hope t open the new wing this summer. During 1913 the in-patients reached a record total of 3056, an increas of 216 on the previous year. The average stay i hospital was 21 days. Out-patients numbered 33,925 a total less than that of 1912 by 4405; this drop i doubtless due to the National Insurance Act, an is welcomed by the committee as tending to intensif the consultative nature of the out-patient department. The ordinary income amounted to £12,697 an increase of over £1000; the ordinary expenditure showed an increase of £336 only, and totalle £16,300. Allusion is, of course, made to the legac of £25,000 in securities left to the hospital by it late president, Mr. Joseph Storrs Fry. The Lor Mayor, who was in the chair, spoke feelingly of th incalculable loss to the hospital and the cit generally in the death of Mr. Fry, but congratulate the institution on securing so worthy a successor i Mr. George A. Wills.

Bristol Insurance Committee.

At the last meeting of this committee the chai man gave an interesting *résumé* of the year's wor so far as medical benefit was concerned. Abou 80,000 insured persons had been treated by th panel doctors, who had issued nearly 400,000 prescriptions. A fact of significance was that at th end of the 12 months only about 600 of the insure had asked to change their medical man. This, a the chairman remarked, was a vindication of th policy of free choice of doctor. The chemist account amounted to £12,800. It was reported tha the medical referee was being temporarily re munerated by the practitioners themselves unti some permanent basis had been decided upon. sum not exceeding £100 was appropriated for healt lectures.

Children's Hospital, Bristol.

The annual report of this hospital showed tha 4873 out-patients and 978 in-patients had bee treated during 1913. The income amounted t £4602 and the expenditure to £5241. Representatives of the employees of some of the largest fim spoke in warm appreciation of the hospital's valu

Lord Mayor of Bristol's Hospital Sunday Fund.

At the first distribution of this fund £1600 wa divided between the medical charities of the cit

The total sum collected to date is £1887, or about £70 less than last year at the corresponding date.

Plymouth Tuberculosis Scheme.

The Plymouth sanitary committee at their last meeting approved a scheme for the establishment of a tuberculosis dispensary, the erection of pavilions for 30 patients on the site of the borough hospital, and the provision of 44 beds at the Devon and Cornwall Sanatorium, Didworthy, or elsewhere. The scheme will involve an annual charge on the rates of about £1623.

Health of Falmouth.

The medical officer of health for Falmouth (Dr. A. Gregor), in his annual report for 1913, states that the death-rate was 13·15 per 1000. The death-rate from phthisis and other tuberculous diseases was 0·52 per 1000. The birth-rate was 17·46 per 1000.

A New Workhouse Infirmary for St. Austell, Cornwall.

At a meeting of the St. Austell board of guardians, held on March 6th, a tender for £3667 was accepted for the erection of a new workhouse infirmary.

Miners' Phthisis in Cornwall.

The medical officer of health for Camborne rural district (Dr. A. Bowhay), in his annual report for 1913, states that during the past 14 years 25 per cent. of the deaths from miners' phthisis had been in men who had previously worked in African mines.

March 17th.

SCOTLAND.

Exemptions from Vaccination in Scotland.

The Secretary for Scotland has given figures showing the number of exemptions from vaccination in Scotland from the passing of the Vaccination (Scotland) Act, 1907, which authorised the making of statutory declarations of conscientious objection to vaccination in Scotland. The numbers of these statutory declarations made in respect of births registered in subsequent years were as follows: 1907, 7258; 1908, 15,846; 1909, 22,746; 1910, 26,954; 1911, 29,582; 1912, 32,863. The figures for 1911 and 1912 have not yet been published, and are subject to revision. This tremendous increase of unvaccinated persons speaks for itself and must necessarily occasion disquietude to the public health authorities.

Treatment of Lead Poisoning.

A very interesting paper on the Electrolytic Treatment of Lead Poisoning was read on March 2nd before the Royal Society of Edinburgh by Sir Thomas Oliver and Mr. T. M. Clague. The authors gave an explanation of the new method of treatment which had been devised by them. This is known as the double electric bath treatment, which is being employed with remarkable success in lead works. The men immerse their feet in a bath of water in which a grid of aluminium is fixed. The hands are placed in a similar bath, also containing an aluminium grid, and the current from an eight-cell accumulator is gradually turned on. The effect of the current is to ionise the lead in the tissues of the person treated, and thus to drive it from one pole to the other, with the result that the person suffering from lead poisoning shows no signs of it after a week or two, while a bath once or twice a week prevents the lead from settling in the system.

Small-pox in Aberdeen.

One of the four cases of small-pox in Aberdeen has proved fatal, the victim being the father of the family who have been attacked, a man of 46, and a mason by trade. So far no fresh cases have been reported.

Dispensaries Closed in Dundee.

At the last quarterly meeting of the Dundee Royal Infirmary it was decided to close the last two remaining dispensaries owned by the infirmary in the city, owing to the small number of patients attending in consequence of the working of the Insurance Act. Arrangements have been made for patients to be seen in the infirmary out-patient room.

Dental Treatment for Children.

At a recent meeting of the Kincardineshire secondary education committee a report was submitted in regard to the proposed dental treatment under the scheme of medical inspection of school children. It was thereupon agreed to engage the services of a dentist at a fee of 7*s.* per case treated. It was estimated that such a scheme would cost £131 per annum.

Aberdeen Insurance Committee: Publication of Doctors' List.

At a meeting of the Medical Benefits Subcommittee of the Aberdeen Burgh Insurance Committee, held on the 9th inst., a letter was read from the Local Medical Committee complaining of the publication of a list of Aberdeen panel doctors, showing the number of patients on each doctor's panel. The committee replied that the list was not officially supplied, and that the publication of it was unauthorised and was regretted by the committee. It is understood that the publication of this list has given rise to considerable indignation among the medical men upon the panel in Aberdeen.

Glasgow Maternity and Women's Hospital.

His Majesty has graciously granted permission for the inclusion in the title of this institution of the word "Royal."

March 17th.

IRELAND.

Radium Institute for Dublin.

THE following committee has been appointed by the council of the Royal Dublin Society to take entire charge of the Radium Institute: Sir Howard Grubb, Professor John Joly, Professor J. A. M'Clelland, Professor J. Mallet Purser, Professor A. Francis Dixon, Dr. W. E. Adeney, and Professor E. J. McWeeney. It is estimated that at least half a gramme of radium will be required, which at the present price will cost from £9000 to £10,000. The Royal Dublin Society has voted £1000, and Lord Iveagh has given an equal sum. The radium is to be kept permanently in the chemical laboratory of the society, the emanation derived being available for therapeutic uses and research by qualified medical men. Medical men receiving the emanation for hospitals are required to present confidential reports as to the results obtained. The emanation supplied for use in a hospital shall not be applied to any but the specified case or cases without the consent of the committee. The charge for emanation will be based on the number of estimated millicuries at the time notified to the purchaser for the removal of the tube from the society's premises.

Civic Survey of Dublin.

In his note added to the recent report of the Departmental Committee on Housing Conditions in Dublin Mr. J. F. MacCabe urged that a civic survey of Dublin should be undertaken before any further housing schemes were adopted. Such a survey would include the consideration of the topography of the city and its surroundings, its means of communication, and industries, as well as the movements, needs, and occupations of the population. It was announced last week that the Local Government Board intends to undertake such a survey without delay.

The Belfast Tuberculosis Scheme.

Dr. J. M. McCloy and Dr. James Shaw have been appointed by the city corporation of Belfast full-time assistant tuberculosis medical officers, the former at £350 and the latter at £250 per annum. Dr. A. Trimble, chief tuberculosis medical officer, is being paid £600 a year.

Scarlet Fever in Newtownards.

At the monthly meeting of the Newtownards board of guardians held on March 14th it was decided to convert the room above the present board room into a temporary ward, owing to the very large number of cases of scarlet fever now being treated in the present fever hospital. Many of the cases have been sent from Comber, where the disease has been extensively epidemic.

Benn Ulster Hospital.

From the report presented to the friends and supporters of the Ulster Hospital for the Eye, Ear, and Throat (established by the late Mr. Benn) at the forty-third annual meeting, held in the institution, Clifton-street, Belfast, on March 11th, it appears that during 1913 there were 2634 new patients, including 424 intern cases. Financially, at the beginning of the year the balance due to the bank was £66 12*s.* 11*d.*, while at the end of the 12 months this was reduced to £16 1*s.* 2*d.*

March 17th.

PARIS.

The "Metro" and Tuberculosis.

The Extra Parliamentary Commission on Tuberculosis, composed of senators, deputies, municipal councillors, and medical men, points out that one of the principal sources of danger as regards the propagation of tuberculosis arises from public vehicles, cabs, motor-buses, &c. The carriages of the metropolitan underground railway appear to constitute the most dangerous focus; for while motor-buses and cabs can be aired and disinfected, the carriages of the "Metro" on most of the lines are never exposed to either light or air, the depôts being all underground. The platforms of the stations are often washed, but the carriages receive only a sweeping. Although spitting in these vehicles is forbidden, the mud brought in on the feet of travellers, the dust, the germs on clothes, are all sufficient causes of infection demanding serious attention. It cannot be absolutely proved that there has been any instance of the propagation of tuberculosis among passengers during the brief period they are in the carriages, but that it is not unlikely is shown by the analogous cases of measles, scarlet fever, and diphtheria which have been contracted on lines having stations close to children's hospitals, whither mothers take their children for consultation. The same has been observed on the motor-bus routes leading to these same hospitals. The medical service of the Metropolitan Company, however, has been struck with the increase in the number of cases of tuberculosis among their employees, especially those who spend the whole day in the carriages and close the doors after each stop. The second-class carriages are frequented, especially at certain times of the day, by a working-class population utterly disregardful of hygienic precautions. These carriages being tightly closed the odour and foul air become very oppressive. To these sources of infection must be added the fact that employees pass nearly the entire day underground, deprived of fresh air and sunlight, without physical exercise, and thus their bodily resistance is greatly lessened. The Commission urges the study of a more efficacious method of airing the carriages and the tunnel itself than that by ventilators at intervals which, by stirring up the air, merely set the dust in motion, with results more distressing than useful. Finally, say the Commissioners, the carriages must be frequently disinfected, and the employees permitted some time off during the day that they may avoid the dangers of a continued sojourn underground.

The Lack of Army Doctors.

The sanitary condition of the army, particularly in the eastern region, where the number of garrisons was abruptly doubled last October, has caused considerable alarm, which has been the subject of much discussion in the Chamber of Deputies. A Commission of Inquiry has visited the new barracks, for the most part hastily constructed, and calls for certain necessary improvements. The particularly rainy winter, the overfeeding of young recruits, and the defective hygienic conditions had led to a recrudescence of the morbidity, which, however, has now completely returned to normal. But a disquieting condition brought to light during the inquiries is the insufficient number of military medical officers, which has been so serious that to fill the vacant posts the Minister of War has had to appeal to the civil doctors belonging to the army reserve and the territorial forces, to retired military medical officers, and even to students of medicine near the close of their curriculum.

Emergency Surgery by Military Officers.

A medical officer from a station in the south of Algeria went afield to perform an amputation at the thigh in the case of a soldier suffering from a serious wound. As the wounded man was cured the commandant of the Algerian army wrote to the medical officer congratulating him on the brilliant result, but requiring the establishment of a course of elementary instruction for officers in the field to enable them to give such urgent aid to their men as appeared essential pending the arrival of the medical officer or the removal of the patient to the nearest medical post, either of which in war time might take up a great deal of time. This note has called forth serious protests from a French journal of military medicine which urges the incompetence of officers to give the needful intelligent medical attention, and the likelihood of danger from their inopportune intervention without a proper diagnosis, which in the event of unfortunate consequences might involve the State in serious pecuniary responsibility.

The Double Xiphopagous Monster.

The separation of double xiphopagus, to which reference was made in my letter in The Lancet of

Jan. 17th, has been necessitated by the fact that one of the children became seriously ill, and, indeed, died two days after the operation. As was suspected, it was found that the fleshy bridge contained a tongue of hepatic tissue common to both organisms. This was ligated without difficulty on both sides. The necropsy on the child that died showed it to be affected with athrepsia, so that it probably lived at the expense of its companion, and would have died sooner but for this union. The surviving child is in excellent health. The death of one of the organisms of a xiphopagus has been frequently noted, separation having been effected on account of ill-health of one of them.

March 16th.

ITALY.

The Hospital Question in Rome.

THE popular agitation about the hospitals of Rome culminated on March 9th in a general strike which lasted for 36 hours in the capital, and was the occasion of scenes of grave disorder and some violence. In a letter two years ago I explained the causes of the crisis in the finances of the Roman hospitals[1] and the appointment of a Royal Commission to re-establish the hospitals on a sound financial basis. The economies practised have proved very unpopular among the people of Rome. The closing of the hospital of San Giacomo and certain accident and emergency stations, "posti di pronto soccorso," has transferred the bulk of the hospital work to the newly erected but inconveniently distant Policlinico outside the walls, with the assistance of four emergency stations within the city. The admission of the poor without payment has been as far as possible limited to those able to produce the official certificate of poverty, and the free distribution of medicines has been curtailed with the utmost strictness. The number of hospital attendants has been reduced and their salaries have been lowered. This last reform led to the explosion of the popular resentment, for the Camera del Lavoro espoused the cause of the *infermieri* and enlisted in their favour the sympathies of the workmen of Rome. But the demonstration of March 9th embraced all parties, when over 100,000 people assembled in the Piazza del Popolo. The commission despatched by the meeting to convey their wishes found the Government in a yielding mood. The hospital of San Giacomo was reopened at 5 o'clock in the afternoon for the treatment of emergencies, with three beds for men and two for women, and six doctors on the staff. Promises were also made that the difficulties in the way of admission to hospital should be lessened and that the rights of the hospital attendants should be considered.

Presentation to Dr. A. R. Coldstream, of Florence.

On March 9th, at the Villa Trollope, Florence, Dr. and Mrs. A. R. Coldstream were the recipients of a presentation from patients and friends of a silver vase, designed and wrought by Mgr. Durst, of the Casa Giudi, and of a cheque for £285, on the occasion of Dr. Coldstream's retirement after more than 30 years' practice in Florence. A large company were assembled for the presentation, which was made by the chairman of the committee responsible for getting up the testimonial, the Rev. Harbut Tanner, who in a felicitous speech recalled the work done in many fields of activity by Dr. and Mrs. Coldstream, and bore witness to the value of their influence upon the life of the Anglo-American community in Florence. Dr. Coldstream, with a speech of anecdote and reminiscence, thanked the company on behalf of himself and Mrs. Coldstream, and a few words from Canon A. A. Knollys brought this *riunione simpatica* to a close.

March 14th.

VIENNA.

Remarkable Increase in the Number of Medical Students.

THE Medical Council of Vienna has issued to all the other Austrian medical councils a circular on the subject of the remarkable increase in the number of students of medicine, as manifested by the fact that there have been 630 new matriculations in the medical faculty for the winter term 1913–14. More students than at any former period are now coming to the University of Vienna from all parts of the Austrian empire and South-Eastern Europe, so that the scientific institutes of the faculty of medicine in this city are unable to deal with the numbers. The Medical Council at length decided to take some steps in the direction of checking this undue multiplication of medical men, and is now seeking information as to the number of practitioners in the district of each Austrian medical council, the number of deaths amongst them, the proportion of them to the population in the various districts, and the number of practitioners required to give the population the benefit of having everywhere an opportunity of consulting properly qualified advisers; other inquiries contained in the circular have reference to the rate of remuneration and the total income of practitioners in various districts. When the replies are received they will be summarised, and the necessary information as regards the prospects of a medical career will be supplied to the schools and colleges. According to all present appearances it is almost certain that the result of this inquiry will be a recommendation that the number of young men taking up the study of medicine should be restricted, and that most of those whose thoughts have turned in that direction should be advised to seek some other vocation.

The Treatment of Septicæmia with the Silver Compound of Methylene Blue.

For some time investigations have been in progress in this city with respect to the treatment of septic conditions with the substance known as methylene blue and its compounds, the supposition being that the affinity of this dye for the pathogenic micro-organisms would render the latter innocuous. At a recent meeting of the Medical Society of Vienna Dr. Arnstein showed two cases treated on these lines. One of them was a woman of 35 years, who after a premature delivery without medical aid developed puerperal sepsis and was brought to the hospital suffering from an occasional rigor, endocardial symptoms, and parametritis complicated with profound anæmia and great weakness. An intravenous injection of 2 decigrammes (3 grains) of the silver compound of methylene blue lowered the temperature a little, and another injection of the same strength on the following day was followed by a fall of the temperature to normal, accompanied by a rapid cessation of all septic symptoms. The other patient was a girl, aged 17 years, suffering from acute polyarthritis and mitral insufficiency with stenosis; she also had a pulse-rate of 110 and received no benefit from aspirin. An injection of the dye resulted in quick relief of the symptoms, although the pathological changes in the heart were of course not affected. Altogether eight cases were treated, the conditions including endocarditis, polyarthritis, erysipelas, general sepsis from a gangrenous appendix, lobular pneumonia, and disease of the hip and knee, probably of tuberculous origin. Out of eight cases only three were not benefited, while the remaining five improved distinctly. It was stated at the meeting that intramuscular injections were not so advisable as intravenous ones, and that it was a good plan to inject first 1 decigramme (1½ grains) and follow it up after one or two days by another injection twice as strong. It was important to have the substance completely dissolved and to use a fresh solution every time.

---

[1] THE LANCET, June 29th, 1912, p. 1782.

The Multiplication of Titles for Medical Men.

Numerous members of the medical profession have of late been granted the privilege of obtaining various titles like "imperial councillor," "medical councillor," and similar high-sounding expressions for use on their doorplates. The system is obviously open to criticism, and is, in fact, not viewed with approval by the bulk of the profession, for as a rule the reasons on account of which such distinctions have been conferred are not very apparent. In the majority of cases the recipients of these titles do not possess any exceptional merits which might distinguish them from their neighbours. The medical authorities have therefore taken the matter up, and it is intended either (1) to endeavour to induce practitioners to refuse to accept any of these minor titles as being derogatory to their professional dignity; or (2) to bring it about that every medical man after having practised for, say, 25 years should receive a medical title like "Medicinal Rath" or something equally designating him as having been engaged in practice for a considerable length of time.

The Treatment of Rabies.

Writing to the Medizinische [illegible] [illegible] or Bujwid discuss[illegible] of patients either [illegible] [illegible]sed to be infected with [illegible] [illegible]ation he gave the results [illegible] [illegible]stitute for rabies in Cracow. [illegible] the anti-rabic emulsion fo[illegible] from the eastern part of ou[illegible] country of Galicia has the largest [illegible] [illegible]ses of rabies in Austria, owing to the low standard of general hygiene amongst the poor population, and to the number of stray dogs, and perhaps also wolves. Thus, since the year 1893, when the institute was opened, and one patient was treated, the number of patients went up rapidly, the figures being 38, 104, 146, 160, 288, 320, 404, 647, 516, 556, 537, 799, 746, 765, 867, 846, 780, 795, 1120, 600. The mortality was very variable, from zero up to 1·7 per cent. (in 1901, 1902, and 1908). After, however, introducing a new virus obtained by 30 passages through rabbits, a "fixed virus" has been prepared and is now available for use; it remains constant in so far as it kills a rabbit in eight days, whilst the previous virus took from 17 to 12 days for its action. By using this "fixed virus," the mortality has been brought down to 0·4 per cent. Such results must be regarded as satisfactory, and as soon as the general population have been brought to realise the necessity of very early treatment there is good reason to hope that nearly every patient infected by a rabid animal will be saved.

CANADA.

New Chancellor for McGill University.

Sir William Macdonald has been elected Chancellor of McGill University, in succession to the late Lord Strathcona. The new Chancellor has been a munificent friend to the institution. On the same day that Sir William Macdonald was elected the board of governors appointed Dr. Geddes a Governors' Fellow of the University, and also announced that Dr. James Douglas, of New York, had given the University $10,000 for a Fellowship in Mining.

Canadian Militia Medical Service Association.

The seventh annual meeting of the Association of Officers of the Medical Services of Canada was held in Ottawa on Feb. 24th and 25th. At the annual banquet on Feb. 24th Lieutenant-Colonel John T. Fotheringham, M.D., of Toronto, presided, and H.R.H. the Duke of Connaught was the guest of the evening. Major D. B. Bentley, M.D., of Sarnia, Ont., Commander of the Fourteenth Field Ambulance, was presented by His Royal Highness with the silver cup given annually by Colonel George S. Ryerson, of Toronto, for the best field ambulance work during 1913. Lieutenant-Colonel R. T. Macdonald, of Sutton, Quebec, was elected president of the association, and Major T. H. Leggatt, of Ottawa, secretary. The Hon. Samuel Hughes, Minister of Militia, has increased the annual grant to the association from $500 to $1000.

Vancouver General Hospital.

It is proposed to add to the Vancouver General Hospital a maternity hospital, an infectious disease building, and administration quarters. The cost of this will be about $700,000. Recently a deputation waited on the British Columbia Government requesting a grant of $250,000; and it was pointed out that quite 50 per cent. of the cases treated in this hospital came from points in the province outside the city of Vancouver, and that more than $1,000,000 had already been spent on this hospital. To this amount the Government had only contributed $35,000.

American Bacteriologists Meet in Montreal.

The meetings of the above were held recently at McGill University. Their society brings together workers in all branches of bacteriology, and is entirely separate from the American Association of Pathologists and Bacteriologists. There were present workers in the bacteriology of water and milk, agricultural bacteriologists, and public health workers. The interest of the meeting centred around the communication of Dr. N. S. Ferry, of Detroit, U.S.A. The reason of this was due to the fact that the lay press had heralded Dr. Ferry as the discoverer of the micro-organism of scarlet fever. What he described, however, was a coccus which he had frequently found in the throats of scarlet fever patients. He has not been able to produce the disease by inoculation of a pure culture of this organism. There was one striking feature in connexion with this announcement—namely, that nurses at the Detroit Contagious Diseases Hospital who had previously been liable to catch the disease from the patients, since Dr. Ferry had vaccinated them with pure cultures of this organism during two years or more had not developed a single case of the disease in their ranks; and it is interesting to add that when Dr. Ferry was absent for a few months, and the supply of vaccine had ceased, some of the nurses who had not been vaccinated contracted the disease.

March 7th.

Obituary.

GEORGE ERNEST HERMAN, M.B. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

WE regret to record the death on March 11th, at his country house in the West of England, of Dr. George Ernest Herman, one of the leading British obstetricians and gynæcologists of the last quarter of the nineteenth century, and a teacher whose influence was carried by his published works far beyond the wide circle of his old pupils at the London Hospital.

Dr. Herman was born on Feb. 8th, 1849. After studying medicine at the London Hospital he qualified M.R.C.S. Eng. and L.S.A. in 1870. In 1875 he obtained the Fellowship of the Royal College of Surgeons, and in 1879 the M.B. degree with honours at the University of London. In 1885 he was elected a Fellow of the Royal College of Physicians of London. Thus, although he never proceeded to the doctorate in his university he was one of the few gynæcologists of his time who held the Fellowship of both Royal Colleges.

In 1876, at the early age of 27, Dr. Herman obtained the post of assistant obstetric physician to the London Hospital, and in 1883 he was promoted to the full staff in succession to Dr. Palfrey. For the next 20 years he continued his active duties of obstetric physician to the hospital and lecturer on midwifery and diseases of women in the Medical School, retiring in 1903, when he was appointed consulting obstetric physician. Apart from his long and honourable association with the London Hospital, Dr. Herman did excellent work as physician to the Royal Maternity Charity and to the General Lying-in Hospital, York-road, Lambeth, and he was also consulting obstetrical physician to the East End Mothers' Home and to the Tower Hamlets Dispensary. In 1893 he was elected President of the Obstetrical Society of London, and in 1886 President of the Hunterian Society, while the Chicago Gynæcological Society conferred on him its honorary Fellowship. As an examiner in midwifery Dr. Herman did much sound work at the English Conjoint Board and at the Universities of Oxford, Cambridge, London, Durham, and Manchester.

But it was mainly by the written word that Dr. Herman's method and manner as a teacher became known to countless numbers of students and practitioners. Something of his own individuality was stamped upon almost every page of the three works which are indelibly associated with his name. His "First Lines in Midwifery" for students and midwives was first published in 1891 and is still deservedly popular, while "Difficult Labours," which first appeared in 1894, has a place by itself on the working practitioner's bookshelf. Herman's "Diseases of Women" was first published in 1898, and has passed successfully through a number of editions, the last appearing two years ago under the joint editorship of the author and Dr. Drummond Maxwell. This work was rightly described by Dr. Herman as a "clinical guide," and, like his previous obstetrical handbook, it was unique in its own field. The influence for good exercised by these two works upon students and practitioners during the past 20 years must have been very great indeed.

Sir Francis H. Champneys writes: "The death of Dr. Herman removes one of the leaders of the branch of obstetrics and gynæcology in our country, after an active and honourable career extended over some 40 years. During practically the whole of this time, or, at least, until his superannuation at the London Hospital severed his connexion with that institution, his work had been continuous, strenuous, and of a high class. His writings showed an active, alert, and singularly logical mind, combined with a wholesome scepticism (in the best sense) which prevented him from accepting current theories, however fashionable, unless facts were found to bear them out. During his lifetime many such fashionable waves have begun—and ended. His style was lucid and pure, with the least shade of a love of archaisms, such as were also dear to the late Dr. Gee; and this probably sprang in both from a habit of reading old books. In neither case did this, however, prevent the author from being thoroughly abreast of his time. Dr. Herman was one of a little band of juniors who in the seventies were, so to say, 'waiting for the consolation of Israel' and who were, therefore, more than ready to welcome the advent of the late Dr. Matthews Duncan to London, an advent which wrought a peaceful revolution in obstetrics and gynæcology in England. To those who are not old enough to remember its condition before that time the change can hardly be described. The writer was much associated with Dr. Herman throughout his career, especially in the Obstetrical Society of London, of which he was all along one of the most useful and active Fellows, and also on various examining boards. His name will long be honourably remembered in the department."

A former colleague at the London Hospital writes: "Only those who were intimately acquainted with Herman knew the man as he really was. His cold and somewhat formal manner and his short and precise way of speaking gave no clue to the kindly feelings or to the breadth of mind that lay beneath. But many of his residents, as well as sisters and students, can testify to acts of kindness done so quietly and naturally that no one seemed to be aware of them; and whene[illegible] colleagues felt that [illegible] As one who was associated with him for many years I have no hesitation in saying that the work he did during the time that the London Hospital Medical College was coming from obscurity into the front was simply invaluable. As a teacher his reputation stood deservedly very high. The opinions that he expressed were the product of his own matured judgment founded on many years of clinical experience; and though a bold and skilful operator himself, he never advocated any measure unless he had first convinced himself that it was necessary and in the best interests of the patient. Few men in his special line of work have earned or deserved a greater or more widely acknowledged degree of respect. He was trusted absolutely by all who knew him."

Dr. Herman married in 1884 Emily, daughter of Mr. T. Gibbings, of Chichester. He leaves four sons, one of whom is a member of the medical profession, and one daughter. For the past few years, since his retirement from practice in Harley-street, he had lived at his country house at Cam, near Dursley, in Gloucestershire.

SIR FRANCIS XAVIER FREDERICK MacCABE, F.R.C.P. Irel.

The death of Sir Francis MacCabe, which we announced last week, occurred on March 3rd at his residence, Sandyford, county Dublin, in his eighty-first year. He was the son of William B. MacCabe, a well-known writer of church history in his time, and was born in Dublin. He received his medical education at the Westminster Hospital, and obtained the Membership of the Royal College of Surgeons of England in 1858. Three years later he received the Licence of the King's and Queen's College of Physicians of Ireland. After a few years' private practice he was appointed resident medical superintendent of the Waterford County Asylum. In 1872 he was transferred to Dundrum Criminal Lunatic Asylum, and in 1876 he gave up lunacy work to become a medical inspector of the Local Government Board. While holding this office he acted in 1879 as a member of the Royal Commission to Inquire into the Sanitary Condition of Dublin. In 1885 Mr. MacCabe left the Local Government Board to become medical member of the General Prisons Board, but in 1888 he returned to the Custom House as medical member of the Local Government Board. In 1892 he received a knighthood and in 1898 he retired. Sir Francis MacCabe brought ability and care to the discharge of his public duties. In private life he interested himself in philanthropic work. He leaves three sons, of whom one is a member of the medical profession.

HENRY GARNETT WILSON, M.B., C.M. Edin.,

LATE PHYSICIAN TO THE GLASGOW HOSPITAL FOR DISEASES OF WOMEN.

Dr. Garnett Wilson, whose death occurred recently, after a long and trying illness borne with great fortitude, studied in Edinburgh and graduated M.B., C.M. at the University in 1882. He proceeded to Glasgow, where he soon acquired a large practice, his patients recognising in him an able medical adviser and a highly sympathetic personality. He was physician to the Glasgow Hospital for Diseases of Women for a number of years, and showed himself both in his hospital and private practice interested in every advance in his profession and a determination to remain up to date therein. He was an expert angler and a good musician, and his company was greatly enjoyed at many medical gatherings, both in Edinburgh and Glasgow. He leaves a wife and two sons, the elder of whom is at present assistant to Professor R. Muir in the University of Glasgow.

Liverpool Eye and Ear Infirmary.—The annual meeting of this charity was held on March 16th, when the committee announced that the revenue for the past year had almost equalled the expenditure. The premises adjoining the hospital, which had been built for a sculptor's studio at the same time as the hospital, and which formed an architectural part of the building, had been purchased. An anonymous benefactor presented the whole purchase money, £1050, and the committee is now appealing for funds to convert the new premises into a much-needed ear department. The appeal is for £15,000, a portion of which is to form an endowment fund.

Correspondence.

"Audi alteram partem."

CHANGES IN THE BLOOD PRESSURE IN THE CAUSATION OF SURGICAL SHOCK.

To the Editor of The Lancet.

Sir,—I have read with much interest Mr. A. Rendle Short's Hunterian lecture on this subject in your issue of March 14th. His lecture clears up several of the debatable points in this difficult and important subject. It is now eight years since I delivered the Hunterian lectures on Shock,[1] and since that time several new theories of shock have been brought forward. Most of these, however, are disposed of as untenable by Mr. Short, but some of the conclusions come to by Mr. Short in his lecture cannot, I think, be allowed to pass unchallenged.

For some five years after delivering the Hunterian lectures I worked on the subject of shock, chiefly from the experimental point of view, with Mr. W. Legge Symes. Unfortunately, owing to the pressure of professional work, I was obliged to give up these researches, and the results have never been published, though some useful results were obtained.

The great difficulty in criticising Mr. Short's paper is the lack of any definition of what he understands by the term "surgical shock." Unless physiologists can agree upon a definition of surgical shock it is obviously impossible to arrive at any conclusions as to the causation of this condition. The clinical definition given by Sir Watson Cheyne and quoted by Mr. Short, excellent as it is, is not sufficient, for although it correctly describes the condition of surgical shock as understood by Dr. Crile and myself, it will also equally well describe the condition of patients suffering from a severe toxæmia. I have found that one of the greatest difficulties in dealing with surgical shock is to distinguish between it and toxæmic conditions. Often, no doubt, the conditions are combined, as, for instance, in the case of patients dying after an operation for intestinal obstruction. It seems almost certain, too, that the condition produced by severe burns is not really one of shock, but is due to a toxæmia, although we do not at present know the nature of the poison.

I cannot agree with Mr. Short that shock is ever seen with contracted blood-vessels, nor do I think he brings forward any reliable proofs of such a condition in his lecture. Experiments on blood pressure which depend upon electrical stimulation of nerves must be accepted with the greatest caution. Mr. Symes and I, after numerous experiments, gave up this method, as we found it was impossible to guard against errors due to stimulation of muscles and sympathetic nerves. The test for shock described by Tyrell Gray and Parsons—based on the theory that stimulation of the sciatic nerve causes a fall instead of a rise of blood pressure—we found was quite unreliable. Mr. Short quotes me as accepting the view that the specific gravity of the blood is raised in shock, but he cannot have seen a paper on Some Points on the *Experimental Production and Control of the* Vascular Atony of Surgical Shock, by Mr. Symes and myself,[2] in which we showed that, on the contrary, the specific gravity falls with the blood pressure. The following extract briefly indicates our conclusions in that paper:—

---

[1] The Lancet, 1905, vol. i., pp. 696, 776, 846.

> Fall in specific gravity of the blood implies transudation of tissue fluid into the blood stream. This is confirmed by the accompanying diminution in percentage of the hæmoglobin. In a cat (2·7 kg.) the hæmoglobin, on the Gowers-Haldane scale, fell from 70 to 58, whilst the specific gravity of the blood dropped from 1048 to 1043. This percentage diminution of the hæmoglobin shows that each 100 volumes of blood was diluted (in round numbers) to 120, which, in conjunction with the accompanying fall in specific gravity of the blood, indicates that the transudate had a specific gravity of 1018—that is, that of average lymph. The reaction of the organism, then, to fall of blood pressure is increase in volume of the blood. That such an increase will tend to restore the lost pressure is obvious. It is, therefore, not unreasonable to regard the reaction as protective, and to infer that transfusion is the logical treatment of the condition.

Mr. Short makes the point that the subcutaneous veins are not dilated in shock and gives this as an argument against the correctness of our theory; but surely it is not. The reason why the subcutaneous veins are found to be empty in surgical shock is that owing to the diminished pressure and feeble circulation the blood does not reach them. I do not think that either Dr. Crile or I ever supposed that the condition of the vaso-motor centres was alone responsible for all the phenomena of surgical shock. The mechanism for maintaining the blood pressure and an adequate circulation is an exceedingly complicated one, depending upon the condition of the muscular structures of the body and on that of many other tissues; and numerous other nerve centres in the neighbourhood of the fourth ventricle are doubtless involved. There is yet much to be learnt with regard to the relative importance of these various centres in the causation of surgical shock; but I believe that in the main the theory originally propounded by Dr. Crile, and adopted by me in 1905, will prove to be the correct explanation of the condition known as surgical shock. The apparent anomalies that are discovered in attempting to explain the phenomena of surgical shock will, I think, be found to be due to the fact that at the present time several distinct conditions are confused under this term.

That Mr. Short's conception of surgical shock is totally different from that of Dr. Crile and myself is shown by his description of the "knock-out blow" as a state of shock. It is, of course, nothing of the sort; the condition produced by a "knock-out blow" is one of collapse and is due to temporary paralysis of all the centres at the base of the brain. This is not in any way comparable to the condition of surgical shock seen after an operation.

I am, Sir, yours faithfully,
J. P. LOCKHART MUMMERY, F.R.C.S. Eng.
Hyde Park place, W., March 17th, 1914.

To the Editor of THE LANCET.

SIR,—In Mr. A. Rendle Short's lecture on the above subject various objections are urged to the view that acapnia causes surgical shock. One of the criteria which appears to the lecturer to be very damaging, if not fatal to the theory, is that the CO_2 content of the venous blood in man shows no fall during shock. But the method of estimating the CO_2 content by Mr. Short is fallacious. His method is to tie a bandage round the patient's arm and then withdraw blood from a vein. Now, immediately after the bandaging the blood below the bandage would absorb an excess of CO_2. Any deduction therefore as to the general content of CO_2 from such a sample of blood is worthless. It may be added that it is the CO_2 content of the arterial blood which is the true criterion. In Yandell Henderson's experiments the CO_2 was always estimated from samples of the arterial blood. I am, Sir, yours faithfully,

Henrietta street, W., March 14th, 1914. A. G. AULD.

THE ACTIONS OF CHLOROFORM AND ETHER ON THE BLOOD PRESSURE.

To the Editor of THE LANCET.

SIR,—As Dr. H. P. Fairlie in THE LANCET of Feb. 28th kindly refers to a remark of my own I should like to make some comment upon his interesting communication. I am the more anxious to do this as I think that his general conclusion, if not controverted and if widely acted upon, is likely to lead to many unfortunate results. This conclusion is that chloroform is a more desirable anæsthetic than ether for long operations or for those where considerable shock is anticipated. Now, in spite of his observations, I would urge that there is an enormous preponderance of evidence from experience in exactly the opposite direction. Nor can his theoretical explanation, quoted from Brown, that chloroform narcotises the vaso-motor cells and ether does not, be accepted; so far as I can see it is pure assumption. Dr. Fairlie does not deny, as indeed the facts prevent him from doing, that with chloroform there is greater fall of blood pressure and more marked shock at the time of operation than with ether. It is afterwards that he believes that ether more often leads to delayed recovery or to fatality. He must bring definite proof of this in a sufficient number of cases before we can assume that chloroform, with its undoubted dangers on the table, is the anæsthetic to be chosen. With modern methods of giving ether and proper use of preliminary alkaloids in suitable cases, the after-effects of ether compare most favourably with those of chloroform; and the delayed recovery that Dr. Fairlie alludes to is, from the nature of the action of the two drugs, far more to be dreaded after long inhalations of chloroform than of ether. In my own experience, as well as in that of many others, ether is especially to be preferred in long and severe operations, and I believe that to encourage the opposite practice would be to lead many inexperienced administrators into difficulties from which they would find it extremely hard to extricate their patients. I am, Sir, yours faithfully,

Harley-street, W., March 16th, 1914. J. BLUMFELD.

To the Editor of THE LANCET.

SIR,—Mr. A. Rendle Short's masterly lecture on Surgical Shock in your issue of March 14th, disposing as it does so effectually of many recent and fascinating theories, is a very complete answer to Dr. H. P. Fairlie's article on Blood Pressure during anæsthesia by chloroform and ether respectively. It is established that, in shock, the left heart and the arteries are empty owing to "bleeding" into the veins of the relaxed muscular system, and the practical corollary is that no anæsthetic should ever be given to such a depth as to relax the muscles completely. As a matter of fact, such deep anæsthesia is necessary very seldom indeed,

---

LEGISLATION FOR INEBRIATES.

To the Editor of THE LANCET.

SIR,—At the time when new legislation for inebriates is before Parliament your leader on the last report of H.M. Inspector under the Inebriates Acts is very opportune. It seems to me, however, that the writer of this article in his endeavour to show the real need for better laws relating to inebriates and better administration of those laws, and in an endeavour to shed more light on the nature of inebriety, actually makes confusion still further confounded in regard to this latter point.

Whilst agreeing with Dr. Branthwaite's definition of "inebriate," as applied to a minority of habitually drunken persons, he objects to its application to those whom he regards as forming the majority of inebriates. These latter he considers to be inebriates, not from psycho-neurotic fault, but rather from environmental conditions. I do not know on what experience of inebriety and of inebriates the opinions are based, but I do know that Dr. Branthwaite's definition, which he calls "*narrow*," *is the result of more than 30 years'* unrivalled experience and close study of every type of inebriate met with in private practice, high-class retreats, and certified inebriate reformatories. My own experience of more than 12 years' work, although restricted to better-class well-educated inebriates, bears him out entirely.

In order to form an opinion as to the mental equipment of an inebriate it is necessary to be intimately acquainted with him both under the influence of alcohol or drugs and during many weeks of enforced or semi-enforced sobriety. My experience of some hundreds of better-class inebriates (both voluntary patients and those who are more or less compulsorily committed under the Inebriates Acts) leads me to doubt whether any one of them can be said to have had anything like a sound psycho-neurotic integrity. While environment plays a very important part in the development of inebriety, it is unquestionably a purely secondary part, persons of sound psycho-neurotic make-up being able to live in similar environments as moderate users of alcoholic liquors.

My experience makes me agree entirely with Dr. Branthwaite's opinion that the fundamental cause of inebriety in nearly all cases is psycho-neurotic fault, defect, peculiarity, call it what you will, generally congenital, but sometimes acquired as the outcome of accident (physical or pyschic trauma) or faulty early training, and that such fault may be trivial, or so apparent as to merit being spoken of as mental defect in the modern acceptation of the term. Whether, however, the majority of inebriates are such owing to psycho-neurotic fault or environmental conditions, the writer of this article, Dr. Branthwaite, myself, and others, who know something of inebriety, all come to the same conclusion—namely, the necessity of further legislation to reach a very large number of inebriates who are out of the reach of existing legislation. Stronger powers are necessary to bring them under satisfactory control and treatment.

Any new legislation for inebriates, such as is suggested by the Bill now before Parliament, must make it possible to reach the curable inebriate far more readily than at present is possible, and the law when enacted must be far more effectually and intelligently administered than is the case with the present Acts, which, ineffectual and gravely deficient as they are, might have been more useful than they have been had they been better administered. There is undoubtedly a better understanding of the real nature of inebriety than there was by the inebriate, his relatives, friends, and his family doctor. With this knowledge better results from treatment are following, due largely to intelligent coöperation on the part of the inebriate and a better understanding of the nature of his trouble. With new legislation dealing with the feeble-minded and with inebriety, as already enacted and comtemplated, real advance should certainly be made in a matter of vital importance to the individual and to the community.

I am, Sir, yours faithfully,
J. W. ASTLEY COOPER,
Medical Superintendent.
The Ghyll Retreat, near Cockermouth, March 16th, 1914.

*** We remain of our already expressed opinion, which was founded upon experience, general as well as particular.—ED. L.

"THE FAMILY ENCYCLOPÆDIA OF MEDICINE."

To the Editor of THE LANCET.

SIR,—It appears to me that the important point in connexion with this matter is being overlooked. The medical profession will readily acquit the eminent authorities whose names appeared in connexion with the publication of any intention of advertising themselves, but it appears to be a fact that they did lend their countenance to an enterprise directly contrary to the best interests not only of the medical profession, but also of the general public. I am, Sir, yours faithfully,

Pembroke, March 16th, 1914. A. HURRELL STYLE.

AN ASSOCIATION OF TUBERCULOSIS MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—The appointment of tuberculosis medical officers having now become general throughout the country it has occurred to me that the formation of an "association" of such officers is a matter worthy of consideration. If such an association came into existence tuberculosis medical officers would be provided thereby with a means of meeting, and thus have the opportunity afforded to them of discussing together and amongst themselves various topics connected with their particular field of labour. This, I think, would be a most desirable thing. It would tend to their mutual benefit and also to the advancement of the treatment of the patients of whom they have charge. Cases could be compared, opinions interchanged, difficulties met with in practice discussed, &c.

Local authorities are framing a general attack upon tuberculosis, and the tuberculosis medical officer is the important factor of the authority responsible for the treatment of the disease in their area. With an association such as I suggest a much greater benefit would accrue from the interchange of knowledge thus afforded than by each individual officer working single-handed in his own field. The object of the attack on the disease is ultimately—and in the shortest possible space of time—to stamp it out altogether. We ought to leave nothing undone which will assist us in our efforts to bring about this result.

In such, then, lies the object of my appeal, and I hope to see some expressions of opinion on the matter in reply thereto. If the general opinion is in favour of an association being founded a preliminary meeting formally to discuss matters in connexion therewith could easily be called. Such an association as I suggest has, I believe, already been formed in Ireland.

I am, Sir, yours faithfully,
J. T. CROWE,
Tuberculosis Medical Officer for Leicestershire.
Leicester, March 17th, 1914.

THE WASSERMANN REACTION.

To the Editor of THE LANCET.

SIR,—The public health committee of the borough of Wimbledon have made arrangements for the carrying out of the Wassermann reaction on behalf of the residents in the district. I am afraid that Dr. L. C. Parkes's arrangements at Chelsea, as set forth in his letter in THE LANCET of Nov. 29th, 1913, would, to a certain extent, defeat his objects, as he demands that the name of the patient shall be supplied. My authority have agreed that no names shall be supplied, so that there shall be no question of anything being revealed. In order to get over the difficulty of Section 133 of the Public Health Act the practitioners are asked to certify (1) that the patient on whose behalf the Wassermann test is being made is a resident within the borough, and (2) that the patient is not in a position to pay the fee for such examination. Thus I think there will be no difficulty which might be encountered if the patients feared that their names were to be given to a third party.—I am, Sir, yours faithfully,

EDWIN H. NASH,
Wimbledon, March 14th, 1914. Medical Officer of Health.

ACUTE SUPPURATIVE OTITIS MEDIA IN SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—May I ask through the medium of your columns for an answer to an important point as regards the infectivity of the pus from the ears of a child suffering from suppurative otitis of scarlet fever? Is this discharge permanently infective and liable as long as it lasts to convey scarlet fever to another person? If not, for how long does such an infectivity last? and when may it be said to be safe to allow a child out of quarantine, though it still has a discharge from the ears?

I venture to think that a clear and authoritative answer to these questions would help many practitioners besides myself.

I am, Sir, yours faithfully,
March 16th, 1914. JOHN MACKERN, M.D. Cantab.

THE TREATMENT OF WARTS.

To the Editor of THE LANCET.

SIR,—In Home and Foreign Notes of the current issue of THE LANCET your Budapest correspondent details a "new" method of treating warts. I have been employing the method (prolonged covering with rubber plaster) for warts and corns for at least eight years, and the idea which originated it explains the mode of action. Eight years ago I had my first Turkish bath, and noted the excessive maceration of the epidermis under the influence of prolonged perspiration. I had then a very painful corn on the sole of my foot, and next day subjected it to prolonged perspiration by applying a star of three little strips of "Z.O." surrounded by a corn ring. Reapplication continuously for three weeks brought out the whole corn in a "wash leather" state, and it has never recurred.

And this "stewing in its own juice" is the least painful as well as the most certain cure for hard corns (and warts). Silver nitrate is the most certain cure for soft corns.

I am, Sir, yours faithfully,
March 13th, 1914. M.B.

THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—I wish to explain why, at the conference of Local Medical and Panel Committees held in London on Friday, March 13th, I asked that Motion 29 on the agenda should contain an expression of opinion that medical referees appointed under the Insurance Act should be non-panel practitioners. In a small area like the Isle of Wight there is not enough work for a whole-time appointment, and doubtless this is the case in many other areas. I take it that in every such area there are non-panel practitioners in touch with the local profession who would gladly do the work entailed providing the conditions are satisfactory; such men would be more independent in their judgment and better able to give an unbiased opinion. Also it is, to my mind, important at this juncture not to widen the breach between the panel and non-panel practitioners. The latter are constantly saying that the Insurance Act has nothing to do with them, and therefore that it is futile for them to belong to various bodies set up under the Act. Why should not this opening be taken to prove that this is not the case? Undoubtedly they will be required in other capacities in the future under the Act as it develops, and I think it is only right to take the first opportunity to further a more sympathetic attitude between panel and non-panel men.

As the chairman of the conference would not listen to what I wanted to point out, and as he would not accept the alteration I suggested in the wording of the motion, I think it is only due to myself and my committees to send this letter to THE LANCET, hoping you may find space for it.

I am, Sir, yours faithfully,
[illegible]
[illegible]
Ryde, I.W., March 16th, 1914.

A FUNDAMENTAL QUESTION IN DIET.

To the Editor of THE LANCET.

SIR,—What effect has cooking on the vitamines? I do not know what they may be, but it is my business to give advice on diets, and I learn (*a*) that they are essential, and (*b*) that they are destroyed by cooking. Therefore I think the title to this note is justified. I am, Sir, yours *faithfully*,

London, March 19th. CIVIS.

⁂ We have re-stated the question in an annotation, hoping that some physiologist may assist us to reply.—ED. L.

AN AGED COUNTESS.—The death of the Countess of Devon, in her 100th year, is announced at Cheltenham. It may be recalled that there is at least one case on record of a titled lady having lived for more than a century—namely, the old Countess of Desmond, who died in 1604 at the reputed age of 140.

THE NATIONAL INSURANCE ACT.

THE FABIAN SOCIETY'S REPORT.

A SPECIAL supplement of the *New Statesman*, published on March 14th, contains the interim report of the committee of inquiry into the working of the National Insurance Act instituted by the Fabian Society Research Department last July. We shall refer to this report in an early issue.

LOCAL MEDICAL COMMITTEE FOR LONDON.

The following is the list of nominations received by the Metropolitan Counties Branch of the British Medical Association for the election of a Local Medical Committee for the County of London:—

Panel Practitioners.

Borough of Marylebone—David Steel Roxburgh and John Pollock Simpson (*contest*).
Borough of Woolwich—Albert Edward Thomson.
Borough of Greenwich—W. H. Reed and Christopher Whewell Hogarth (*contest*).
Borough of Deptford—William Henry Payne.
Borough of Bermondsey—Benjamin Arthur Richmond.
Borough of Southwark—J. V. C. Denning.
Borough of Lambeth—Herbert Taylor.
Borough of Camberwell—George Beckett Batten.
Borough of Wandsworth—A. C. B. Biggs.
Borough of Battersea—John Theodore Richards.
Borough of Fulham—John Fletcher.
Borough of Chelsea—John James Orr.
Borough of Hammersmith—J. A. Butler.
Borough of Kensington—Herbert Henry Mills.
Borough of Paddington—John Alexander Angus.
Borough of Westminster—Albert Ernest Cope.
Borough of St. Pancras—Thomas Marshall.
Borough of Islington—J. J. A. Sherry.
Borough of Stoke Newington—Alfred Welply.
Borough of Hampstead—E. Claude Taylor.
Borough of Shoreditch—David Livingston Hamilton and Major Greenwood (*contest*).
City of London—John James Scanlan.
Borough of Holborn—Michael Joseph Ryan.
Borough of Finsbury—Robert Drummond MacGregor.
Borough of Hackney—Thomas Francis Keenan.
Borough of Bethnal Green—G. Henderson.
Borough of Stepney—W. Owen Williams and Percy T. Goodman (*contest*).
Borough of Poplar—H. J. Cardale.

Non-Panel.

Three nominations were required for each group of boroughs, except Marylebone, for which one only was required.

Marylebone—Charles Wynn Wirgman.
Group I. Woolwich, Greenwich, Deptford, Lewisham—No nominations.
Group II. Bermondsey, Southwark, Lambeth, Camberwell—No nominations.
Group III. Wandsworth, Battersea, Fulham, Chelsea—No nominations.
Group IV. Hammersmith, Kensington, Paddington, Westminster—W. H. Burnhill and Wilfred Kingdon.
Group V. St. Pancras, Islington, Stoke Newington, Hampstead—No nominations
Group VI. Shoreditch, City of London, Holborn, Finsbury—J. H. Porter and W. F. Roe.
Group VII. Hackney, Bethnal Green, Stepney, Poplar—A. G. Southcombe, Gilbert Nicholson, and M. C. Corner.

Six Representatives of the Medical Staff of Hospitals.

W. McAdam Eccles, Thomas Watts Eden, James Galloway, N. Bishop Harman, Vincent Warren Low, Lauriston E. Shaw, Fred. J. Smith, George Robertson Turner (*contest*).

One Poor-law medical officer.—H. E. Garrett.

One medical officer of health.—No nomination.

One registered medical woman.—Mina Dobbie.

NATIONAL MEDICAL UNION.

In reference to the resolutions circulated on March 12th by the London Organisation Committee of the National Medical Union to all practitioners resident in the County of London and not on the panel, repudiating the action of the Metropolitan Counties Branch of the British Medical Association in attempting to elect a Local Medical Committee for London, we have been asked to publish the following statement of the position taken up by the National Medical Union:—

The proposals of the Metropolitan Counties Branch are made with a view to the committee so to be elected obtaining statutory recognition by the Insurance Commissioners as "representative of duly qualified medical practitioners resident in the county," such committee when elected and recognised to have the duties mentioned in Section 62 of the Insurance Act of 1911.

Section 62, 1911, *reads as follows*:—

Where a Local Medical Committee has been formed for any county or county borough or for any area for which a District Committee has been formed and the Insurance Commissioners are satisfied that such committee is *representative of the duly qualified medical practitioners resident in the county*, county borough, or such area as aforesaid, they shall recognise such committee, and, where a Local Medical Committee has been so recognised, it shall, subject to the Regulations made by the Insurance Commissioners, be consulted by the Insurance Committee or District Committee, as the case may be, on all general questions affecting the administration of medical benefit, including the arrangements made with medical practitioners giving attendance and treatment to insured persons, and shall perform such other duties, and shall exercise such powers as may be determined by the Insurance Commissioners.

The Amending Act, Section 32, of 1913, provided that the opinions and wishes of the medical practitioners who have entered into the agreement should be ascertained by Insurance Committees through Panel Committees representative of the panel practitioners. Such Panel Committee has been formed in London, and it is further to be noted that by the Amending Act it is made eligible for recognition as the Local Medical Committee above described in Section 62 of the principal Act.

The London Organisation Committee of the National Medical Union bases the recommendations announced in its circular on two grounds: 1. The numerical basis of the election proposed by the Metropolitan Counties Branch renders it quite unrepresentative of the whole profession resident in the County of London, and on that ground it would be ineligible for statutory recognition and illegal if recognised. 2. The duties and sphere of action of the Panel Committee and Statutory Medical Committee respectively in London being as above described, and the situation with regard to panel and non-panel practitioners in London being what it is, the London Organisation Committee of the National Medical Union regards the attempt by the Metropolitan Counties Branch to set up a statutory committee on the above lines as calculated to involve the non-panel practitioners in London in an appearance of lending support to the present arrangements for medical benefit under the Insurance Acts, whereas, as a matter of fact, their aim and object is to proclaim and evince in every possible way their determined opposition to the same.

NURSING UNDER THE INSURANCE ACT.

At a conference convened at Westminster by the Association of Approved Societies Sir Victor Horsley, as chairman of a subcommittee appointed to consider a scheme for the nursing of the insured, submitted the outlines of a proposal. The committee considered that the Commissioners should set up a special nursing fund comparable in constitution and administration to the special mileage fund. The Approved Societies could not, as a whole, add nursing benefit to existing benefits, and the need was urgent. The report was received but not adopted, the discussion showing that delegates present were not authorised by their societies to support the proposals made.

DERBYSHIRE INSURANCE COMMITTEE.

At a recent meeting of the Derbyshire Insurance Committee it was reported that the Insurance Commissioners had allocated £1000 out of their special fund to the county for mileage for practitioners whose patients lived in distant or inaccessible places. It was asked whether certain sanatoriums had refused to receive patients who had not been vaccinated. The county medical officer of health, Dr. Sidney Barwise, replied that these were private institutions carrying out their own rules. The question was then asked whether when the county sanatoriums were built there would be a like refusal with regard to admission to them. To this the clerk to the committee answered in the negative, but a member insisted upon a reply from Dr. Barwise who answered that "people would have to obey the law." A report of the Sanatorium Subcommittee recommended the committee to pay to the county council for sanatorium treatment for insured persons, and for their dependents recommended for sanatorium benefit by the committee, at the rate of 7½*d.* per insured person per annum. This was discussed and referred for further consideration to a joint committee representing insured persons and the county council.

THE LEICESTER UNION OF MEDICAL PRACTITIONERS.

At the second annual meeting of the Union, held at the Public Medical Service Buildings, Leicester, Dr. R. Wallace Henry was elected president, Mr. J. B. Pike vice-president, and Dr. A. V. Clarke treasurer. The secretary reported that the membership had increased during the year by 105. Arrangements had been made to enable members to obtain without any charge legal advice on matters connected with the relations between themselves and their patients, to have debts collected, and insurances effected on extremely favourable terms. The treasurer reported that there was a balance in hand of £132 18*s.* The committee was authorised to consider the desirability of federating with the National Medical Guild. The meeting was followed by the annual meeting of the Leicestershire and Rutland Public Medical Service which is managed by the Union. Reports were presented from the various subdivisions of the service which showed that there were over 80,000 subscribing members (uninsured persons); that the year's work had been done under conditions which were satisfactory alike to medical men and patients, and that the financial results were most satisfactory. Suggestions for further improving the work of the service were referred to the committee.

A MEDICAL PRACTITIONER VINDICATED.

Hasty and undeserved censure has frequently been applied to the medical profession in connexion with work done under the Insurance Act, particularly with regard to alleged malingering. In a proved case of malingering, for which a sentence of a month's hard labour was recently imposed at the West Ham police-court, the magistrate was reported as having said that he would have imposed a more severe sentence if the prisoner had not apparently "been encouraged in his offence by a gentleman in a responsible and honourable position." The prisoner was stated to have earned over £10 in wages during a period in which he was drawing 10*s.* a week sick benefit upon a succession of medical certificates, and although in a newspaper report before us no names are mentioned, it is obvious that the magistrate's censure was directed against the medical man on the panel who gave the certificates. A few days later the magistrate, Mr. R. A. Gillespie, again mentioned the case and made a handsome retractation of his observations so far as they referred to the medical practitioner, saying that they were based upon statements made on behalf of the prosecutors. He further said that investigation had shown that the remarks made by the prosecuting advocate were in no way justified, and that the following resolution had been passed by those charged with the inquiry: "That this committee having heard the statement of Mr. John Jordan Harvey, express their sympathy with him and their unabated confidence in his honour and integrity, and undertake to use every effort to get him publicly vindicated." Mr. Gillespie was pleased to say that he was able to come to the same conclusion that the doctor's certificates were *bonâ fide*, and that he had no reason to believe that he in any way assisted the prisoner in his false representations. Mr. Harvey is to be congratulated upon the prompt and satisfactory manner in which his reputation has been cleared, and credit should also be given to newspapers, which refrained from mentioning any name in a case in which it was clear that one side only had been heard.

AN INQUIRY AT THE INSURANCE COMMISSION.

On Friday and Saturday mornings of this week public inquiries are being held at the National Insurance Commission, Buckingham-gate, into the desirability or otherwise of retaining two medical practitioners upon their respective panels.

"SURPLUS FUNDS" IN LONDON.

At a well-attended meeting of panel doctors with small lists, held on Tuesday, March 17th, at 12, Thayer-street, W., the following resolutions were passed:—

1. That a committee be formed to arrange for a deputation (*a*) to members of the Government, or (*b*) to the Insurance Commissioners, or (*c*) to the Insurance Committee, or to more than one of them, in order to represent to them that the requirements of the Insurance Act, 1911, in respect of the allocation or assignment of insured persons to doctors on the panel are not being carried out; to inquire why they have not been carried out; and to ask what alternative proposals, equitable to the doctors working the Act, are put forward by these bodies.
2. That this meeting of the London panel doctors asks the Commissioners not to sanction the agreement arrived at between the London Insurance and the Panel Committees as regards the allocation of surplus funds, on the grounds that the agreement does not take into consideration the responsibility incurred by doctors on the panel for treating unallocated persons as required by the Medical Benefit Regulations. The meeting is of opinion that this responsibility does not vary directly with the size of a doctor's list.
3. That this responsibility be measured for each quarter by the number of new patients accepted for treatment during that quarter, and that the unallocated funds be divided in proportion to these numbers.
4. That copies of these resolutions be sent to the Commissioners, the London Insurance Committee, the Panel Committee, and to the medical press.

Only a limited number of men voted for resolution 3, which was carried by a small majority. The feeling of the meeting was absolutely for the exclusion from participation in any surplus funds of all doctors with 2000 or more persons on their lists.

The meeting was convened by Dr. A. R. Eates, who acted as temporary honorary secretary.

FAILURE TO EXAMINE A PATIENT.

At an inquest held recently at Westminster it was proved that the deceased, a foreman sewerman, had complained of pain in the abdomen and had been given a bottle of medicine by his panel doctor. He became worse and had paid another visit to the same gentleman, who had then given him a different medicine, telling him that he was suffering from rheumatism, but had not at either visit made any examination of the patient, who later was taken ill at his work and died in a cab on his way to hospital. Post-mortem examination showed that there had been tuberculous cavities in both lungs and a verdict of death from natural causes was returned, *the jury adding that they wished to censure the* panel doctor for failing to make an examination. This censure the coroner endorsed, expressing the opinion that if a medical man undertook to attend insured persons it was his duty to do his work with thoroughness.

Medical News.

UNIVERSITY OF BRISTOL.—At the Second Examination for the degrees of M.B., Ch.B., held recently the following candidates were successful:—

Frederick Christopher Ashley Frith, Douglas Leonard Lees, George Strickland Lewis, and Arthur Denis Symons.

Dr. Nierenstein, lecturer in bio-chemistry, has been appointed to deliver a short course of lectures in Immuno-chemistry during the month of May.

UNIVERSITY OF LONDON.—Dr. Frederick Taylor has been reappointed a member of the General Medical Council for 1914–15, and Sir William Collins, K.C.V.O., has been appointed representative of the University at the celebration of the 300th anniversary of the foundation of the University of Gröningen in June and July next. The followi[illegible] been appointed staff examiners for 1914–15: Bac[illegible] L. S. Dudgeon; Anatomy, Mr. A[illegible] and Professor A. Melville Paterson; An[illegible]), Professor A. Keith, F.R.S.; Forensic Medi[illegible] Dr. William A. Brend and Dr. E. P. Manby; M[illegible] Dr. Norman Dalton, Dr. Humphry Davy Rolleston, Dr. [illegible]. B. Warrington, and Dr. James Galloway; Mental Diseases and Psychology, Dr. Maurice Craig and Dr. William McDougall, F.R.S.; Obstetric Medicine, Dr. Henry Russell Andrews and Professor Walter C. Swayne; Pathology, Professor Robert Muir, F.R.S., and Professor F. W. Andrewes; Pharmacology, Professor A. R. Cushny, F.R.S., and Dr. James A. Gunn; Physiology, Mr. Joseph Barcroft, F.R.S., and Professor E. H. Starling, F.R.S.; State Medicine, Dr. John William Henry Eyre and Dr. Thomas Morison Legge; Surgery, Mr. Frédéric F. Burghard, Mr. William F. Haslam, Mr. Henry Betham Robinson, and Mr. William Turner; Tropical Medicine, Professor F. M. Sandwith and Professor Sir Ronald Ross, K.C.B., F.R.S. Mr. H. L. Eason has resigned his membership of the external council. A course of eight lectures on the Rate of the Blood-flow in Man in Health and Disease will be given in the physiological laboratory of the University, South Kensington, by Dr. G. N. Stewart, professor of experimental medicine, Western Reserve University, Cleveland, U.S.A., at 5 P.M., on Tuesdays, May 5th, 12th, 19th, and 26th, and June 2nd, 9th, 16th, and 23rd, 1914. A University studentship in physiology will be awarded to a student qualified to undertake research in physiology, and will be tenable in a physiological laboratory of the University or of a school of the University. The studentship will be awarded annually if a candidate of sufficient merit shall present himself, but no student is eligible for re-election.

UNIVERSITY OF CAMBRIDGE.—Mr. V. C. Pennell, now at St. Thomas's Hospital, has been elected to a Fellowship at Pembroke College. The following medical degree has been conferred: B.C., F. W. Watkyn-Thomas, Trinity. On March 14th the grace in favour of applying to the Board of Education for a Government grant to the medical school of the University was adopted by the Senate. The placets numbered 268, the non-placets 235, giving a majority of 33 in favour of applying for the grant.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The honorary secretaries of King Edward's Hospital Fund for London have received, from the executors of the late Sir Julius C. Wernher, Bart., securities to the value of £269,644 7*s.* 2*d.*, being a first distribution on account of the one-twelfth share of the residuary estate bequeathed by him to the capital account of the Fund. The probable total amount which will accrue under this bequest is £465,000. This is in addition to a specific bequest of £25,000.

THE ASSOCIATION OF PUBLIC VACCINATORS OF ENGLAND AND WALES.—The annual dinner of this association was held at the Royal York Hotel, Brighton, on March 14th, the President, Mr. George Jackson, of Plymouth, being in the chair. After the usual loyal toasts the President, in proposing the toast of "The Association," said that it was established in 1898 and had since continued its career of usefulness with varying support. There were at present 630 members out of 3500 public vaccinators. This was not so large a proportion as they had had, or as they ought to have. The public effect of the association would be greatly enhanced if more joined them. He thought it would be well to consider whether a much larger number would not be gathered in even at the cost of a reduced subscription. The man who had perhaps only a dozen or so of vaccinations in a year was hardly likely to realise the importance of the association. Mr. Jackson spoke in warm terms of the service rendered by Dr. Arthur Drury, of Halifax, whose combating of the argument of Dr. W. R Hadwen before the Manx Commission on Vaccination had undoubtedly materially contributed to what he considered one of the most important of recent steps in the fight—viz., the rejection of the conscience clause submitted by the House of Keys. As it was, there was all over the country an accumulation of dangerous material that would sooner or later overwhelm all sanitary precautions. He referred to some of the grievances of their body, not the least of which was insecurity of tenure, so that public vaccinators were liable to dismissal almost at a moment's notice. Dr. A. E. Cope, of Westminster, in responding, told how the idea of the society had been suggested to him in 1897 by the Local Government Board inspector who was inspecting his vaccinations, who pointed out the great service it could render not only to the public vaccinators themselves, but to the authorities. After consultation with Dr. Mitchell, of Lambeth, and Dr. James, of Bermondsey, a meeting was called which resulted in the formation of the association, with Dr. E C. Greenwood as first president. He eulogised the literary work done by Dr. Drury to bring the work of the public vaccinator before the country. He quoted a parable in which a parallel was drawn between fireproofing and vaccination, between fire brigades and sanitation. No matter to what a pitch of perfection we might carry our fire brigades and appliances, we must not give up our fireproofing. Mr. Arthur Maude, the retiring president, proposed the health of his successor in the chair, Mr. George Jackson, whom he described as the backbone of the profession in the West of England, whose services to the British Medical Association had been very great, and who had represented the profession as one of its elected Members on the General Medical Council. Mr. Jackson acknowledged the toast before leaving. Mr. Maude then took the chair, and Dr. Drury gave the toast of "The Visitors." They were proud to have with them, he said, Dr. S. Monckton Copeman, of the Local Government Board, Dr. W. Ainslie Hollis, President of the British Medical Association, and Dr. Henry Gervis, chairman of the local division of the association, Dr. D. Forbes, medical officer of health for Brighton; Dr. J. F. G. Dill, senior physician, and Mr. R. F. Jowers, *senior surgeon*, of the Royal Sussex Hospital; besides the representatives of the medical press and other visitors. Dr. Hollis replied briefly, and Dr. Gervis also replied, and said that when he was applied to by conscientious objectors he always advised them to read the old novels. In modern novels the hero or heroine died of "brain fever," or went off in a "decline," but in the old novels, which dealt with pre-vaccination times, the ever-present fear with every one was the small-pox. He said that the vaccinators represented the vanguard of the treatment of the future, which looked as though it would consist of inoculation therapy. The public vaccinator would ultimately supersede the parson, for in the time to come the immoral man would be vaccinated from a highly moral character to cure his diseased morals. His hearers might laugh, but stranger things had happened. A good musical programme was provided.

LITERARY INTELLIGENCE.—The new catalogue of the W. B. Saunders Company, revised to February, 1914, forms a useful guide to the publications of this firm. The descriptions of books on medicine, surgery, dentistry, nursing, and veterinary practice are accompanied in many cases by specimen illustrations, and the indices of authors and subjects make reference easy. The catalogue will be sent post free to members of the medical profession on request.—Messrs. Longmans and Co. announce for early publication a new book, by Professor W. M. Bayliss, entitled "Principles of General Physiology," which will treat of the fundamental properties of animal and vegetable cells and organisms, somewhat on the lines of the "Phénomènes de la Vie," of Cl. Bernard.

ROYAL SANITARY INSTITUTE.—A provincial sessional meeting will be held at Birmingham on March 27th and 28th. On the opening day, in the University, a discussion will take place at 7.30 P.M. on "The Certification of Milk and its Effect on the General Milk Supply," to be opened by Mr. Wilfred Buckley, who will be followed by Professor A. Bostock-Hill, M.D., Mr. J. Malcolm, F.R.C.V.S., Dr. George Reid, and Dr. John Robertson. General discussion is invited The chair will be taken by Dr. Louis C. Parkes. Tickets for admission of visitors may be obtained from Dr. J. Robertson, medical officer of health, Council House, Birmingham, who is acting as the local honorary secretary of the meeting, and of Mr. E. White Wallis, secretary of the Institute, 90, Buckingham Palace-road, London, S.W.

ABERDEEN MATERNITY HOSPITAL.—At the annual meeting of this hospital held on March 10th it was reported that many Approved Societies under the National Insurance Act were paying 10*s.* for cases treated in the hospital and 7*s.* 6*d.* for cases treated outside by the staff and visiting nurses. In this respect the Aberdeen Hospital seems to have fared better than any other of the Scottish hospitals. A movement was in progress to bring all the Scottish hospitals into line in relation to the Act. The number of cases treated in the hospital during the year was 185, a decrease of 56 on the previous year; in the patients' homes 111 cases, a decrease of 151 on the previous year, were treated. The falling off in numbers, especially of district cases, was undoubtedly the result of the Insurance Act, some of the outside patients being under the impression that if they went into hospital they would lose their money benefit. The maternity hospitals in Edinburgh, Glasgow, and Dundee had been affected proportionately in the same manner. Twenty-three nurses in training passed through the hospital during the year, all receiving their certificates. Forty-three students attended during the year and the amount received in fees was £135 9*s.*

NELSON HOSPITAL FOR WIMBLEDON AND MERTON.—The annual meeting of the supporters of this institution, being the new building of the South Wimbledon, Merton and District Cottage Hospital, was held on March 16th, when a very satisfactory report was presented. A comparison of the accounts of 1911, the last year in the old building, with 1913, the first year in the new, showed that the hospital's income had actually doubled, in accompaniment with the work done. In 1911 there were 14 beds and cots; in 1913, there were 26 The expenditure in 1911 for maintenance purposes was £673 0*s.* 9*d.*, in 1913 it was £1378 5*s.* 3*d.*, while the corresponding income had risen from £685 10*s.* 3*d.* to £1415 19*s.* 8*d.* In addition a sum of £1758 17*s.* 6*d.* had been received for the building fund. The need for extension has already become manifest, for although there are at present only 26 beds, on several occasions in 1913 28 patients have been accommodated. The supporters of the hospital are therefore urged to relax no effort in obtaining funds for the maintenance and the future enlargement of the hospital. The year 1914 has opened well, for already a cheque for £250 has been received towards endowment, and other promises have been made.

UNIVERSITY COLLEGE HOSPITAL.—The annual general meeting of members of the corporation of the hospital will be held on Tuesday, March 26th, in the board room, at 3 30 P.M. The agenda include the election of a President, Vice-Presidents, Treasurer, and other officers, and consideration of the reports upon the condition and prospects of the hospital and medical school respectively, and accounts of the income, expenditure, and property.

THE SPITAL SERMON.—The annual Spital Sermon will be preached at Christ's Church, Newgate-street, London, on Wednesday, April 22nd, at 3 o'clock, before the Lord Mayor and Corporation of the City of London and the governors of the five Royal Hospitals (St. Bartholomew's, St. Thomas's, Christ's, Bridewell, and Bethlem) The preacher will be the Right Rev. Watkin Herbert Williams, Bishop of Bangor.

THE VICTORIA HOSPITAL, BLACKPOOL.—An awkward situation has arisen at this hospital owing to the summary dismissal by a subcommittee of the board of management of the hospital of two nursing sisters who had given information, in answer to invitation, with regard to the food-supply to the residents in the institution. The medical board of the hospital, finding that the dismissal of the nurses had been too drastic, and considering them as having had no intention to be disloyal to the matron, asked the board of management to reconsider their course of action. This the board of management refused to do, and after an abortive conference between the subcommittee and the medical staff, four of the five members of the medical staff handed in their resignations, to take effect a month from that day—namely, Jan. 11th, 1914. One local practitioner was obtained to partly fill the gap, and a second who lived near was for a time enlisted. He has since resigned. The hospital with 80 beds and a corresponding out-patient department appears at present to be staffed by one of the original staff, and by his partner who has since been appointed to one of the vacancies, with the assistance of a new house surgeon. A meeting of the local practitioners at Blackpool has resulted in a resolution supporting the attitude of the resigning members of the medical staff. The local practitioners have pledged themselves not to accept any appointment at the hospital until there is a complete reorganisation of the board of management, while their resolution adds "that all future appointments should be open to the profession generally."

ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.—At the annual court of [illegible] of this institution recently held, with the Lord [illegible] Johnston Wallace) in the ch[illegible] charity, which was [illegible] upon the institution wer[illegible] Mayor pointed out that d[illegible] ber of [illegible] and that there was a waiting [illegible] ore the house committee [illegible] request for authority to [illegible] ds necessary to extend the hospital and to maintain it when extended. He foreshadowed a prospective appeal to the public for this purpose to the extent of £100,000. After the report had been adopted Mr. John Cairns moved a special resolution expressing strong disapproval of the proposal contained in Clause 1 of the Bill shortly to be presented to Parliament to extend the Truck Act, whereby an employer is prevented from making any deduction from the wages of workmen in respect of subscriptions or payments to any hospital. The resolution authorised the house committee to take such steps as seemed necessary to secure an amendment of the clause. Some £20,000 are provided annually by the workmen, and both the proposer of the resolution and his seconder made it clear that if the clause in the Bill were passed as it stood it would inflict a most serious blow on the infirmary. The resolution was carried unanimously. In the report itself it is stated that the average number of patients per day was 411·65, and the average stay 17·65 days. The attendances in the out-patient department were 101,736, as compared with 113,862 in 1912. The cost per patient was £4 10*s.* 11*d.*, as compared with £4 11*s.* 6*d.* in 1912, and the cost per occupied bed was £94 0*s.* 6*d.*, as against £89 6*s.* 2*d.*

ABERDEEN DISPENSARY.—At the annual meeting of the Aberdeen Dispensary held on March 10th it was reported that the number of cases dealt with had dropped by nearly 43½ per cent. since 1911. It was, therefore, agreed that the number of medical officers be reduced from six to five, the vacancy which fell to be filled at this time being left unfilled and the district rearranged to suit the new arrangement. The total number of cases treated at the dispensary during the year was 7387, compared with 9310 in the previous year. Attention was drawn to the decrease in the number of primary vaccinations performed during the year. The conscientious objectors' clause had led to an enormous reduction of vaccinated children throughout the country.

QUEEN'S HOSPITAL, BIRMINGHAM.—The seventy-third annual report of this institution for the year 1913 shows that there has been a reduction in the number of out-patients, of whom 31,674 were treated, as against 36,217 the previous year. This is accounted for by the number of trivial and less important cases which are now treated by panel doctors. The number of in-patients was 3013, or a small reduction over last year. The income was £10 847, against £11,868 in 1912 (which included a contribution of £1000). The expenditure was £17,554, as compared with £16,871 the previous year. The actual deficit on the year's working was £6707 0*s.* 2*d.* The hospital treated no fewer than 6249 insured persons as out-patients and 969 as in-patients. Most of these were sent to the hospital by panel doctors for special treatment or operation. It is stated in the report that during the year 58 subscribers withdrew, and 10 reduced their subscriptions, giving the Insurance Act as the reason.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Condition of the Blind.

AN Interdepartmental Committee is to be set up to inquire into the condition of the blind. This subject was discussed in the House of Commons on Wednesday, March 11th, and an interesting statement on it was made by Mr. HERBERT LEWIS, the Parliamentary Secretary to the Local Government Board, who spoke for the Government.

Mr. LEWIS in the course of his remarks said that honourable Members had been told that there were 34,000 blind persons in the United Kingdom. The number of blind people in proportion to the total population had shown a steady decrease since the year 1851. Women were less subject to blindness than men were except at a very advanced age. Of the whole population 760 out of every million males were blind, but the number amongst females was only a little over 700. Out of the total number of blind persons of the age of 10 years and upwards 35 per cent. of the men were occupied, as against only 9 per cent. of the women, and these figures showed that the need of finding occupation was much more acute in the case of the women than of the men. It had been said in the course of the debate that the only thing which the State had done for the blind was action in regard to the disease known as ophthalmia neonatorum. That statement did not cover the whole ground. Parliament had passed the Elementary Education (Blind and Deaf Children) Act, 1893, and it provided for the compulsory education of the blind from the ages of 5 to 16. Under that Act accommodation was provided for 2400 blind children at 41 day and residential schools, and there were more than 1900 on the registers of those schools. The Home Office had also done something to abate the evil of blindness. Optic neuritis was in the past a very frequent feature of lead poisoning in pottery work, but the Regulations which had been made by the Home Office requiring the removal of dust and periodical medical examination of the workers had been so effective that at present practically no cases of this kind at all had been reported. The Insurance Act would in the course of a few months enable a large number of blind people to receive benefit. The action of the Local Government Board in reference to the compulsory treatment of ophthalmia had been referred to. At present 36 per cent. of the blindness amongst school children was due to this disease. The action which had been taken by the municipalities under the voluntary powers which they possessed had been conducive to the very best possible results. Very few cases indeed occurred in which children were afflicted with blindness when proper precautions had been taken, and he trusted that the action of the Local Government Board to be taken at an early date would have the effect throughout the country of greatly lessening the suffering and loss of sight which this disease caused at the present time. With regard to the work of the Board of Education in preventing defective eyesight, let him say that school inspection had done a great deal in this direction. Extra guidance in the use of the eyes in school work had been given. Spectacles had been provided, and it would be agreed that preventive work of this kind was the very best description of work which the department could undertake. Having spoken of the excellent work done by voluntary institutions for the blind, he said that what the Government proposed to do at the earliest possible moment was to appoint an Interdepartmental Committee to consider the whole question of the condition of the blind. The necessity for such an inquiry would be admitted on all hands. The report on the Census for 1900 recommended that expert opinion should be taken as to what constituted blindness. From the inquiries which had been made prior to 1911 it appeared that there were many diverse opinions as to how blindness should be defined. A definition which had met with a certain amount of international acceptance and employment and must have therefore some degree of continuity was possible, but the English experts considered it inadequate to the requirements. That showed that it was obviously necessary in the first instance to inquire as to what the definition was. Then it was necessary to collect statistics which would have to be obtained from a variety of sources, and it would not be easy to obtain all the required information. For example, there were some charities which were partially for the blind and partially for other purposes. Then information would have to be ascertained with regard to the sufficiency of accommodation in the various institutions. The committee would have to make some estimate of the effect of the Insurance Act upon its work and would have to ascertain the number of old age pensioners who were blind. That information was not at present available from the Census returns. And there was also the important question whether some use could not be made, whether by means of correlation or otherwise, of the funds which were now in the hands of charities who at the present moment were doing their best to carry out their philanthropic duties in the best possible way. Parliament would require to have all this information and, he had no doubt, more information upon this question. He, however, wished to make it perfectly clear that this inquiry was not to be instituted with a view to postponing the consideration of the question, but rather with a view to expediting it. The inquiry would be set up at the earliest possible moment. He was bound to say on behalf of the Government that they could not anticipate what the findings of the committee would be, and they could not at the present moment give any undertaking on the points that would come within the scope of the inquiry.

The Navy and the Medical Professson.

Two points of medical interest are noted by Mr. CHURCHILL, the First Lord of the Admiralty, in his explanatory memorandum on the navy estimates. He mentions that a civilian oculist has been added to the medical consultative board to advise on questions arising as to the eyesight in the navy, and the services of Sir John Tweedy, F.R.C.S., have been secured for the first appointment. It is mentioned that a new branch of the Royal Naval Volunteer Reserve is being formed of medical students who have completed a certain portion of their training but are not fully qualified medical practitioners. These officers will be styled surgeon probationers, and it is hoped that will prove later on a valuable addition to the reserves of medical officers. The surgeons probationers will rank with sub-lieutenants R.N.V.R.

Assistants to Chemists and Druggiſts (Qualification) Bill.

Mr. GLYN-JONES has presented a Bill in the House of Commons "to make provision with regard to the compounding of medical prescriptions by assistants to persons, firms, or bodies corporate entitled to carry on the business of a chemist and druggist." It has been read a first time.

Nurses' Registration Bill.

The text of the Nurses' Registration Bill recently introduced by Dr. CHAPPLE in the House of Commons has been published. Its objects and aims have been embodied in a memorandum. That document states that hitherto no minimum standard of knowledge for professional nurses has been defined or enforced. The object of the Bill is to ensure that the community shall have a guarantee that the nurses they employ are skilled in their professional duties, and through standardisation to give security to the public that the services of fully qualified nurses shall be readily obtainable.

It is further explained in the memorandum that the Bill *establishes* a "General Council for the Registration of Nurses in the United Kingdom," composed of persons appointed by the Privy Council, the Local Government *Boards in the United* Kingdom, associations of registered medical practitioners, and direct representatives of the nursing profession.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 11TH.

School Clinics in Monmouthshire.

[illegible] officers showed that in a large percentage of cases the treatment afforded *had* been *effective*. The Monmouthshire education authority had established a clinic *at Newport for treating defects of the eyesight.* They had under consideration the establishment of further school clinics. It was estimated in the school medical officer's report for 1912 that the number of children in the area between seven and eight years with defective vision was 1294 out of 10,535, or 12·3 per cent., and that the number of children between five and eight years with defective teeth was 22,242 out of 22,683, or 98 per cent. He (Mr. Trevelyan) was, of course, not responsible for these figures, nor was he in a position to say how long it would take to deal with these cases.

Treatment of Tuberculous Patients.

Mr. HUME-WILLIAMS asked the President of the Local Government Board how many hospitals *or other institutions* intended for the care of the sick had been commandeered for the purpose of tuberculosis patients under the National Insurance Act; and what arrangements had been made for *the housing elsewhere of the patients for whose benefit those* institutions were intended at the time when they were so [illegible]
are rem [illegible]
required [illegible]

Avoiding Risk of Spreading Infection.

Mr. ASTOR asked the President of the Local Government Board to state in how many instances in the last three years had local authorities taken power through clauses in local Acts to compensate persons for giving up their employment at the request of the medical [illegible]
avoid the risk of spreading infec[illegible]
wrote in reply: Twelve local [illegible] three years obtained power by local Act to compensate persons for giving up their employment at the request of the council or of the medical officer of health for the purpose of preventing the spread of infectious disease. In addition seven local authorities have obtained power by local Act during the same period to compensate dairymen who cease to supply milk, and two to compensate common lodging-house keepers *for* the closing of their lodging-house under similar circumstances.

THURSDAY, MARCH 12TH.

Medical Inspection in Irish National Schools.

Mr. O'DONNELL asked the Chief Secretary to the Lord [illegible] only £263 2*s.* 6*d.* was spent, the balance being returned to [illegible] £5000 was voted, but [illegible]
[illegible] uned. The con-
[illegible] ntributed by the

MARRIAGES

KEIR—OAKEY—On March 10th, at St Mary's Parish Church, Eastbourne, Ivan Cochrane Keir, M D, to Olive Madeline Oakey youngest daughter of the late John and Sophia Oakey, of Surbiton and Folkestone

DEATHS

DEWAR—On March 11th, at his residence, 56 Fernleaf street Moss Side, Manchester, James Dewar, F R C S Edin, in his 78th year

ELLIOT.—On March 16th, after a short illness, George Stokoe Elliot, M.D, F R C S E, of Southwell, Notts, in his 77th year

HAWKINS—Very suddenly, at 73, London street, Reading, Francis Henry Hawkins, M.D, M.R.C P.

HERMAN.—On March 11th, at Cam, Gloucestershire, George Ernest Herman, M B, F R C P, late of Harley street, W., aged 65

PRITCHARD—On March 13th at "Holmby," Albert road, Bognor, Trevor John Pritchard, M B

N. B—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

HEALTH OF THE LEEWARD ISLANDS.

IN his report for 1912–13, just received at the Colonial Office, the Governor (Sir H. Hesketh Bell, K.C M G.) states that the year under review was fortunately free from all atmospheric disturbances, and was only marred by an inadequate rainfall. The general health of the population was good, though much still remains to be done for the im- [illegible] litions among the labouring [illegible] of females is very marked in [illegible] umbering only 55,000, as com- [illegible] us of 1911 [illegible] Barbuda, [illegible] lla, 4075; Dominica, [illegible] 1; Virgin Islands, 556 [illegible] patients (as against [illegible] itted into the hospitals of the colony, and there were 384 deaths, as against 348 for 1911. There are two leper asylums in the colony—one at Rat Island, in Antigua, and the other at Fort Charles, in St Kitts In the former there were 33 lepers (15 males and 18 females) at the beginning of the year; 1 male and 2 females were admitted during the year, and 3 females died. There is no record in Antigua of any [illegible] d leprosy. The [illegible] Dominica, sup- [illegible] maintained on an average 10 paupers [illegible] ministrator of St. Kitts [illegible] ate was 38 46 and the [illegible] atients treated in the [illegible] ver and 56 from yaws. [illegible] health of the popula- [illegible] he year, but there is [illegible] infants notwithstand- [illegible] to instruct parents in [illegible] For those—Europeans [illegible] d the elementary laws [illegible] hy as any part of the [illegible] months is delightful." [illegible] sioner of Montserrat, gives the birth-rate there as 34 03 and the death rate as 13 97 per 1000; and in [illegible] Mr. T. L. E. Clarke, M I [illegible] the birth-rate was 38 and [illegible]

RECUMBENT INVALID LIFTERS.

A CATALOGUE issued by Mr. Skeffington, of Ulundi-road, Blackheath, S E, illustrates several of his useful contrivances, some of which are in use in our various hospitals and institutions, for dealing with invalids who are compelled to adopt a recumbent position. The invalid lifters are made in several types, and by their means, amongst other advantages, a patient can be prevented from slipping down towards the foot of the bed, thereby avoiding the difficulty, especially with a heavy patient, of getting him back again into a comfortable position; an invalid can be raised into a sitting posture, and there maintained, without exertion on his part or on the part of the nurse or attendant, for any period desired; a patient can be lifted, as on a hammock, bodily above the bed, so that the bed can be re-made underneath or a bed-pan be placed in position; a soiled sheet can be changed without distressing the patient or causing any loss of muscular energy, and without turning the patient on one side, as is customary; a typhoid patient can be given a bath by lowering him in his sheet into a collapsible bath placed on the bed; and a patient can be placed in practically any desired position without having recourse to the more or less dangerous practice of "tilting" the bedstead. These invalid lifters, which were awarded a gold medal at the recent International Congress of Medicine, can be hired or purchased outright; and anyone who has to do with a case in which the patient has to adopt a recumbent position will be interested in this catalogue of practical appliances for the comfort and convenience of invalid and nurse.

J. A. S.—Insured persons have the right to change their source of medical treatment at the end of the year. The regulations are elaborate and our correspondent should study them. They can be purchased through any bookseller for 3½*d*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

Walton: Variations in the Growth of Adult Mammalian Tissue in Autogenous and Homogeneous Plasma (communicated by Prof. W. Bulloch).—Mr. E. C. Grey: (1) The Decomposition of Formates by B. Coli Communis; (2) The Enzymes which are Concerned in the Decomposition of Glucose and Mannitol by B. Coli Communis (communicated by Dr. A. Harden).—Surgeon-General Sir D. Bruce, Major A. E. Hamerton, Captain D. P. Watson, and Lady Bruce: Description of a Strain of Trypanosoma Brucei from Zululand—Part I., Morphology; Part II., Susceptibility of Animals.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SPECIAL MEETING OF FELLOWS: at 5 P.M.

Lecture:

Surgeon-General Gorgas on his Work at Panama.

SECTION OF ODONTOLOGY (Hon. Secretaries—Robert McKay, F. Coleman): at 8 P.M.

Paper:

Dr. T. J. Horder: Dental Sepsis from the Point of View of the Physician.

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—H. Batty Shaw, John Fawcett): at 5.30 P.M.

Papers:

Dr. J. A. D. Radcliffe and Dr. D. L. V. de Wesselow: The Diagnosis of Pulmonary Tuberculosis.

Professor Theodore Schott (Nauheim): Recent Investigations on the Changes induced in the Circulatory Apparatus by Physical Methods of Treatment.

SECTION OF PSYCHIATRY (Hon. Secretaries—R. H. Cole, Bernard Hart): at 8.30 P.M.

Special Meeting (in conjunction with the BRITISH PSYCHOLOGICAL SOCIETY).

Paper:

Dr. H. Devine: The Biological Significance of Delusions.

Discussion:

On Dr. R. G. Rows' paper—The Importance of Disturbances of the Personality in Mental Disorders.

THURSDAY.

SECTION OF NEUROLOGY (Hon. Secretaries—T. Grainger Stewart, H. Campbell Thomson): at 8.30 P.M.

Paper:

Dr. David Orr and Dr. R. G. Rows: Experimental Infection of the Central Nervous System (with lantern demonstration).

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—F. Langmead, Philip Turner, W. J. Midelton): at 4.30 P.M.

Cases:

Dr. E. A. Cockayne: (1) Ocular Torticollis; (2) Defective Development of Vertebræ and Ribs.

Mr. C. Max Page: (1) Hirschsprung's Disease; (2) Two Cases of Achondroplasia.

Dr. R. A. Chisolm: Spastic Diplegia.

Mr. Philip Turner: Multiple Exostoses.

Dr. J. Walter Carr: Specimen of Cirrhotic Liver with Perihepatitis.

Dr. F. G. Crookshank: (1) Congenital Heart Disease (? Patent Ductus Botalli and Pulmonary Stenosis); (2) Case of "Murmur."

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Paper:

Mr. Major Greenwood, jun., and Mrs. Frances Wood: Changes in the Recorded Mortality from Cancer and their Possible Interpretation.

MEDICAL SOCIETY OF LONDON, 11, Chandos street, Cavendish-square, W.

MONDAY.—8.30 P.M., Sir StClair Thomson: Three Years' Sanatorium Experience of Laryngeal T[illegible] Tonsils and Adenoids in Child[illegible]

PLYMOUTH MEDICAL SOCIETY, Athenæum Chambers, Athenæum-lane, Plymouth.

WEDNESDAY.—8 P.M., Clinical Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Lumleian Lecture: Dr. J. A. Ormerod: Some Modern Theories concerning Hysteria. (Lectures II. and III)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies street, W.C.

MONDAY.—4 P.M., Dr. G. N. Meachen: Clinique (Skin). 5.15 P.M., Lecture:—Dr. N. Pitt: Intrathoracic Aneurysm.

TUESDAY.—4 P.M., Dr. E. B. Smith: Clinique (Medical). 5.15 P.M., Lecture:—Dr. T. G. Stevens: The Operative Treatment of Uterine Displacements.

WEDNESDAY.—4 P.M., Mr. M. Heath: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Donelan: Some Forms of Nasal Obstruction and their Consequences.

THURSDAY.—4 P.M., Mr. E. R. Carling: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. C. McClure: The Serum Treatment of Consumption.

FRIDAY.—4 P.M., Mr. H. Tilley: Clinique (Ear, Nose, and Throat). 5.15 P.M., Lecture:—Dr. W. Wingrave: Suppuration.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein [illegible] 2 P.M., Medical and Surgical Clin[illegible] Operations. Dr. Pritchard: B[illegible] 2.30 P.M., Mr. Dunn: Diseas[illegible]:—Dr. Bernstein: Diseases of the Blood.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Bernstein: Diseases of the Blood.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., [illegible] Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical [illegible] Gynæcological (Dr. Banister). [illegible] R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological [illegible] (Dr. A. E. Giles). [illegible] Clinics:—Medical Out-patient (D[illegible] (Mr. Carson); [illegible]

FRIDAY.—2.30 P.M. [illegible] Out-patient (Dr. A. G. Aul[illegible] Eye (Mr. R. P. Brooks). 3 P.M., [illegible] ppel).

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON). Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on Syphilology:—

TUESDAY, WEDNESDAY, AND FRIDAY.—4.15 P.M., Dr. H. Head: The Nervous System.

The Schorstein Memorial Lectures (in the Anatomical Theatre):—

THURSDAY.—4.15 P.M., Dr. H. Head: The Clinical Aspect of Syphilis of the Nervous System.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4.30 P.M., Lecture:—Dr. Habershon: The Diagnosis of Early Pulmonary Tuberculosis.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

FRIDAY.—5 P.M., Lecture-Demonstration:—Dr. M. Leslie: Pleurisy.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

QUEEN'S HOSPITAL FOR CHILDREN, Board Room of the Hospital, Hackney-road, N.E.

MONDAY.—4 P.M., Demonstration:—Dr. A. E. Gow: Medical Cases.

[illegible] EAR HOSPITAL, Gray's [illegible]

[illegible] Diseases of the Larynx [illegible] and Fallacies regarding [illegible]

CANCER HOSPITAL Museum of the Hospital, Brompton, S W

Post Graduate Lectures on the Diagnosis and Treatment of Cancer —
WEDNESDAY.—5 P M , Mr Knox The Roentgen Diagnosis of Internal Growths

ROYAL INSTITUTE OF PUBLIC HEALTH, Lecture *Room* of the Institute, 37, Russell square, W C

Course of Instruction for Tuberculosis Officers School Medical Officers, Medical Practitioners &c —
FRIDAY —5 P M , The Diagnosis and Treatment of Tuberculosis &c — Lecture XI —Dr H O West A Co ordinated Scheme

MANCHESTER HOSPITALS POST GRADUATE CLINICS

TUESDAY —SALFORD ROYAL HOSPITAL —4 30 P M , Dr Heywood [illegible] estmacott : Sup [illegible] Melland Some Slight Ailments

FRIDAY —ROYAL EYE HOSPITAL—4 30 P M , Dr H H McNabb Cases for Diagnosis

For further particulars of the above Lectures, &c , see Advertisement Pages

A DIARY OF CONGRESSES

THE following Congresses Conferences and Exhibitions are announced In 1914 —

[illegible]

" 15th-18th (Berlin) —Forty third Congress of the German Surgical Society
" 19th-21st (Berlin) — 'Jubilee Congress of the German Röntgen Society
" 20th 23rd (Wiesbaden) —Thirty first German Congress for Internal Medicine
" 27th-May 1st (London, Royal Horticultural Hall) —Nursing Conference and Exhibition
May 1st-Nov 1st (Lyons) —International Town Hygiene Exhibition
May (London Imperial Institute) —Victoria League Imperial Health Conference
May October (London, Shepherd's Bush) —Anglo-American Exposition
June 18th-24th (London, Church House Westminster) —International Conference on the Blind
July 6th 11th (Blackpool) —Twenty ninth Congress of the Royal Sanitary Institute
" 8th-10th (Oxford) —Ophthalmological Congress
" 8th-13th (Edinburgh) —Congress of the Royal Institute of Public Health
" 21st-23rd (Chester) —British Pharmaceutical Conference
" 27th-31st (London).—Fifth Annual Session of the Clinical Congress of Surgeons of North America
" 28th-31st (Aberdeen) —Eighty second Annual Meeting of the British Medical Association
Aug 3rd-8th (London) —Sixth International Dental Congress
" 10th-15th (St Petersburg) —Twelfth International Congress of Ophthalmology
Sept 7th-12th (Berne) —International Congress for Neurology Psychiatry, and Psychology

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub Editor "

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager "*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1913 were given in THE LANCET of Dec 27th, 1913

VOLUMES AND CASES

VOLUMES for the second half of the year 1913 are now ready Bound in cloth, gilt lettered, price 16*s* , carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2*s* , by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, London, W C , are dealt with by them ? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions post free from THE LANCET Offices have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year ..	£1 5 0
Six Months	0 12 6	Six Months .	0 14 0

Hunterian Lecture

ON

THE PHYSIOLOGY AND PATHOLOGY OF UTERINE HÆMORRHAGE.

Delivered before the Royal College of Surgeons of England on Feb. 13th, 1914,

By H. BECKWITH WHITEHOUSE, M.B.,
M.S. Lond., F.R.C.S. Eng.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS, ENGLAND; HONORARY ASSISTANT GYNÆCOLOGIST AND ASSISTANT CLINICAL LECTURER ON DISEASES OF WOMEN, GENERAL HOSPITAL, BIRMINGHAM, ETC.

(*With Illustrative Plates.*)

Mr. President, Ladies, and Gentlemen,—My first pleasant duty is to thank you for the honour you have conferred upon me in appointing me one of your Hunterian professors for the current year.

INTRODUCTION.

In selecting Uterine Hæmorrhage as the subject of this lecture I have been guided mainly by two factors. In the first place, it affords me the opportunity of placing before you the results of some researches in which I have been engaged. Secondly, the present appears to be an appropriate time for discussing some of the older views upon uterine bleeding based principally upon clinical observation, in the light of that more exact knowledge which scientific study and laboratory experiment have placed at our disposal.

John Hunter himself was much interested in the phenomena associated with the blood and its coagulation, as is shown by the publication in 1792 of his "Treatise on the Blood." This fact in itself provides another very good reason why we should choose that organ of the body where hæmorrhage is not only a pathological but a physiological function to form the basis of a lecture founded in his memory.

Uterine hæmorrhage, however, in all its varied aspects is far too large a question to take up in the time at my disposal. I propose, therefore, to limit remarks upon pathological bleeding to its incidence apart from pregnancy and uterine neoplasms. Such hæmorrhage is sometimes termed idiopathic, to denote the absence of gross physical signs. A clear understanding of the facts underlying pathological bleeding must rest upon a true interpretation of the phenomena associated with physiological hæmorrhage, and therefore the first portion of the lecture is devoted to facts concerned with the etiology and physiology of the function known as menstruation.

PHYSIOLOGICAL UTERINE HÆMORRHAGE.

The Relation of Menstruation to Pro-œstrum.

Matthews Duncan once observed that "menstruation is like the red flag outside an auction sale. It shows that something is going on inside." This is obviously true, but we may pause to ask whether such bleeding is physiologically necessary to the sexual economy. A comparative study of the mammalia shows that uterine hæmorrhage is by no means an essential but merely a concomitant of the sexual cycle and is associated with those anatomical changes to which Heape has applied the name of pro-œstrum. There is abundant evidence that a phenomenon in all essentials identical with menstruation in the human female occurs in the case of the lower mammals. Attention was first drawn to the similarity between menstruation and pro-œstrum by Wiltshire in 1883. More recently the excellent work of Heape and Marshall and Jolly have confirmed the views originally set forth.

It is not my wish to go into detail upon this subject, which has been so admirably treated by other workers. It is sufficient to point out that in most animals the stage of pro-œstrum is marked *by the presence of a discharge from the generative* canal. In some, such as the rabbit and the rat, this discharge consists simply of the secretion of the uterine glands with a small quantity of degenerated epithelium. In others, of which the cow, mare, sheep, goat, pig, and cat are examples, this discharge is occasionally mixed with blood. Domesticity and high breeding tend to increase both the frequency of the sexual cycles and the amount of the attendant bleeding. Thus, in the bitch a well-marked hæmorrhagic discharge is almost invariably present during pro-œstrum, and the blood is as concentrated as that recorded for monkeys. In works upon veterinary science numerous references both to physiological and pathological bleeding in the case of animals are to be found. Fleming, for example, observes that in the case of the cow "the hæmorrhagic flow appears two or three days after the commencement of rutting. The amount of blood does not exceed one or two ounces, and the coagulated clot remains in the vagina until it is expelled with the urine."

In the case of the primates the recognition of a regular and periodical menstrual discharge is of great antiquity. In fact, it is recorded by Dr. Mead that the ancient Egyptians painted the cynocephalus *to represent the moon* "*upon account of a certain* sympathy whereby the female of this animal has evacuations of blood from the uterus at the new and full moon." The subject of menstruation in the higher apes has been fully investigated by Heape, and his researches prove clearly that the pro œstrum of primates is identical in kind with that of other mammals and is analogous to menstruation in the human female. The differences observed in individual species are only *one of degree, relating* either to occasional or regular rupture of vessels in the uterine mucosa, and partial or complete denudation of the latter. A comparative study of pro œstrum from the lowest to the highest mammals shows a progressive development until in the primates and the human female the function reaches its highest state of development. Periodical uterine hæmorrhage is, in fact, one of the sacrifices which women must offer at the altar of *evolution and civilisation.*

The Menstrual Clot.

A study of the changes through which the uterus passes at each pro-œstrum reveals the interesting fact that in the great majority of those animals where this stage is characterised by a flow of blood from the endometrium, a definite and well-marked clot is formed in the body of the uterus. In fact, Heape, in his classification of the internal phenomena of pro-œstrum, accords the *formation* of the menstrual clot a definite place as one of the essential stages. In the case of the monkey he observes that "with the blood which is poured out from the ruptured lacunæ is mixed always degenerated epithelial cells, together with stroma tissue and the superficial portion of the uterine glands, the whole forming a more or less dense clot which in some cases entirely fills the uterine cavity. During the period of recuperation this clot is expelled." This is the case also in lemurs, but in the bitch no blood clot is formed. The physiological phenomena and anatomical appearances of the endometrium during pro-œstrum in the latter animal have been investigated in detail by Retterer, who notes that extravasation of blood in the mucosa occurs, but there is no denudation of the epithelium. It is a point of some interest, therefore, that a clot occurs where there is destruction of epithelium, or, in other words, where a definite breach of surface exists.

Menstrual Discharge in the Human Female.

As is well known, the normal menstrual discharge when it escapes from the vulva is a dark-red fluid containing epithelial débris, degenerate uterine glands, and leucocytes. It is usually stated that the blood does not clot. By some this is supposed to be due to dilution with the uterine and cervical secretions. It has also been stated that the mucous secretion from the cervix is the cause of the non-coagulation of the menstrual blood. In 1912 Blair Bell published a detailed analysis of retained menstrual fluid obtained from 12 cases of hæmatocolpos. In this material he found that fibrinogen and fibrin were absent, and therefore attributed the non-coagulation of menstrual blood to the absence of these constituents. On the other hand, in August, 1913, in a paper read before the Seventeenth International Congress of Medicine, J. Riddle Goffe attempted to show that the absence of coagulation was due to the presence of antithrombin in the menstrual blood. It is evident, therefore, that, although the fact of non-coagulation has been accepted, opinions are divided as to its causation.

A fluid similar in general appearance to that contained in hæmatocolpos is the coffee-coloured content of ovarian blood cysts. I therefore had a similar analysis made upon this material, and found that both fibrinogen and fibrin were again absent. A hæmoglobin derivative and very degenerated red cells were present, showing that the material primarily contained blood. A striking difference between the two fluids was the entire absence of calcium salts in the contents of the blood cyst and the superabundance of the same in hæmatocolpos fluid, as shown by Blair Bell. In the contents of an ovarian blood cyst that I recently investigated a small solid mass was present in the brown grumous fluid. This was investigated for fibrin by Weigert's method of staining, and small traces of this substance were present. In the rest of the fluid fibrin was absent. I am therefore led to the proposition that in the living body an enzyme or substance of this nature exists which has the power of digesting fibrin and breaking down blood clot. I hope to show, moreover, that a similar body or "fibrinolysin" plays a very important rôle both in the physiology and pathology of uterine hæmorrhage.

Since the formation of a menstrual clot is such a usual and common phenomenon amongst other species of mammalia, it was a matter of surprise to me that such should not be the case with the human female. The first investigation that I made, therefore, was to institute an inquiry amongst women as to the frequency with which they themselves had noted, at some time or other, the occurrence of clots or solid material in the normal menstrual discharge. The menstrual histories of 120 apparently healthy women were [illegible] and of these 62 acknowledged that either occasionally or regularly they noted "clots" in [illegible] fluid. As a general rule these clots were [illegible] and unless a definite inquiry was made the fact [illegible] not observed by the patient, who usually [illegible] that "the fluid did not clot." From this [illegible] therefore, approximately 50 per cent. of [illegible] normally note the presence of clots in the discharge. The existence of these clots in the fluid proves that all the machinery for the coagulation of blood is complete.

It may not be out of place, in view of the [illegible] to follow, to state briefly the current [illegible] concerning the clotting of blood. [illegible] Morawitz showed that normal blood plasma [illegible] a globulin, fibrinogen, together with calcium [illegible] and a substance of unknown composition [illegible] prothrombin or thrombogen. The [illegible] is [illegible] condition of adsorption in the fibrinogen [illegible] When blood leaves the vessels and is brought into direct contact with tissue cells it encounters a body known as thrombokinase. This substance, which varies in amount in different tissues, promotes the union of thrombogen and calcium salts to produce thrombin. The latter then exercises a quantitative action upon the fibrinogen, converting it into fibrin, the proteid which forms the organic basis of all clot. Excess of thrombin is inactivated by a hypothetical body called antithrombin normally circulating in healthy blood. It is obvious therefore that deficient or delayed coagulation may be produced by the individual absence of fibrinogen, prothrombin, calcium salts, thrombokinase, or excess of antithrombin.

An attempt to demonstrate the presence of excessive antithrombin in the non-menstruating [illegible] menstruating endometrium and also [illegible] menstrual fluid, failed in every case in [illegible] experiments which I undertook in conjunction with Dr. Gwynne Maitland, lecturer on physiology [illegible] versity of Birmingham. The results of [illegible] experiments are detailed in Table I. [illegible] vinced us that excess of antithrombin is [illegible] cause of non-coagulability of menstrual fluid.

The occurrence of a well marked clot in [illegible] these experiments points to the absence of antithrombin either in the endometrium [illegible] secretion. Menstrual blood [illegible] for experimental purposes [illegible] the vagina by placing the blades of a Sims's speculum into the posterior [illegible] the patient lying in the Sims's [illegible] From material thus collected I have been able to convince myself that, although small clots are not infrequently present in the discharge, in the majority of cases the material is quite fluid and in essential details coincides with the analysis given by Blair Bell in the case of hæmatocolpos fluid. The points to which particular [illegible] are: (*a*) the absence of fibrin; (*b*) [illegible] of fibrinogen; (*c*) the high proportion of calcium salts; and (*d*) the large number of leucocytes and occasionally lymphocytes scattered amongst the degenerated cells of the uterine epithelium and glandular débris. Normal menstrual blood in the vagina is faintly alkaline, and gives the spectrum of oxyhæmoglobin. Hæmolysis is practically always present.

Material collected in the vagina, however, has very different characters from that taken directly from the uterus. In the first place, I venture to assert that *with the healthy and normal* *endometrium clotting always takes place within the uterine cavity.* This fact became evident to me when attempting to obtain menstrual fluid unmixed with the secretion from the cervical glands. The technique employed was as follows. The patient was placed in the semi-prone position and the posterior vaginal wall retracted with the broad blade of a Sims's speculum. The anterior lip of the cervix was seized with volsellum forceps and the cervix sterilised by iodine. A glass catheter of the shape and size indicated in Fig. 1 was introduced through the cervical canal into the corpus uteri. Where hæmorrhage is in progress this is a procedure of the greatest ease, and if the periodic flow is well established blood flows slowly into the tube. Within a few seconds, however, the stream ceases and an examination of the tube shows that the lumen is blocked by blood clot. Altogether 30 cases of normal menstruation have been examined by this means, usually upon the second day of the period when the flow is greatest, and in every case thrombus has been present in greater or less amount in the uterine cavity. In only 8 of these cases could fibrin be demonstrated in the blood present in the vagina. These details are represented in tabular form in Table II.

At first I attributed this unexpected finding to direct trauma of the endometrium, but the continued presence of thrombi in spite of increased care in obtaining the blood, and the employment of tubes previously immersed in liquid paraffin, has convinced me that the phenomenon is physiological and a part of the menstrual cycle. In many cases the thrombus contains epithelial débris formed by breaking-down tissue from the endometrium, and so is analogous to the menstrual clot to which I have already referred in the case of primates. The microscopical appearances of a fragment of degenerated endometrium obtained from the menstrual clot are represented in Fig. 2. Since thrombi are not present in the fluid when it reaches the vagina, or if present are so small as almost to pass unnoticed, it is evident that during its passage from the corpus uteri to the lower genital passages fibrin becomes partially or completely dissolved. This autolysis is analogous to the phenomena I have referred to in the case of ovarian blood cysts, and in my opinion is the result of an enzyme of a fibrinolytic nature.

Evidence of a Specific Thrombolysin in the Uterine Secretion.

The question now arises as to whether it is possible to demonstrate the existence of such an enzyme by more conclusive tests. The experiments shown in Table III. were carried out with this in view. Menstrual blood collected from (*a*) the uterus and (*b*) the vagina was mixed in varied proportions with blood taken from the basilic vein. The coagulation time was noted and the tubes incubated at body temperature. The results are detailed as under:—

TABLE III.—*To show Thrombolytic Power of Menstrual Blood.*

10	1 ,, (hetero).	½ ,,	4 ,,	Partial.	24 ,,
11	1 ,, (auto).	¼ ,,	4½ ,,	,,	24 ,,
12	1 ,, (hetero).	¼ ,,	5 ,,	,,	24 ,,
13	2 ,, Control.	—	4½ ,,	*Nil.*	24 ,,
14	2 ,, ,,	—	5 ,,	,,	24 ,,

In Table III. "auto" signifies that the venous blood and menstrual blood were collected from the same patient; "hetero" that the venous blood was taken from another patient. The coagulation time was estimated by Wright's coagulimeter method and also directly in test tubes. In the experiments quoted the coagulation times indicate that thrombosis was complete and that the test tube containing the mixed bloods could be inverted without the contents escaping.

With regard to the results, it will be noted that in the case of menstrual blood of vaginal origin the coagulation time of the mixture varied from 2 to 5 minutes. The resulting clot was resolved completely in 6 experiments and partially in the remaining 6 in times varying from 12 to 24 hours. With menstrual blood collected directly from the uterus coagulation occurred in from 2 to 4 minutes, the average time being 2·8 minutes. The resolution of clot took place completely in 7 cases and partially in the remaining 5. It should be noted, however, that in the latter, clot was already present before a further quantity of blood was added. With the controls no breaking down of clot occurred, and the coagulation time varied from 4½ to 5½ minutes. In those cases where resolution of the clot is recorded as complete the fluid was centrifugalised and the deposit stained for fibrin by Weigert's method. An important fact indicated in the table is that autolysis occurred *not only* with the patient's own blood, but *also* with that from another patient. The phenomenon is best marked where menstrual blood is in excess. When venous blood is in excess fibrinolysis is only partial.

A further series of experiments were undertaken to ascertain whether the substance present in menstrual blood, which possesses this power of disintegrating thrombi, acts in a quantitative manner or as a true enzyme. The results are detailed under Table IV., the object of these experiments also being to ascertain whether the fibrinolysin is in the fluid or solid portion of the menstrual discharge.

TABLE IV.—*To show Thrombolytic Power in the Fluid obtained by Centrifugalising Menstrual Blood.*

Series 1. Menstrual Blood (Vaginal). Fluid only.

Experiment	Venous blood.	Menstrual fluid.	Coagulation time.	Clot resolved.	Time.
1	1 c.c.	3 c.c.	3 min.	Complete.	12 hours.
2	1 ,,	2 ,,	2 ,,	,,	24 ,,
3	1 ,,	1 ,,	3 ,,	Partial.	24 ,,
4	1 ,,	½ ,,	4 ,,	,,	24 ,,
5	1 ,,	¼ ,,	3 ,,	*Nil.*	24 ,,
6	1 ,,	¼ ,,	5 ,,	,,	24 ,,
7	2 ,, Control.	—	5 ,,	,,	24 ,,
8	2 ,, ,,	—	5½ ,,	,,	24 ,,
Series 2. Menstrual Blood (Uterine). Fluid only.					
1	1 c.c.	3 c.c.	3 min.	Complete.	24 hours.
2	1 ,,	2 ,,	3 ,,	,,	12 ,,
3	1 ,,	1 ,,	2 ,,	,,	6 ,,
4	1 ,,	½ ,,	4 ,,	Partial.	24 ,,
5	1 ,,	¼ ,,	4 ,,	*Nil.*	24 ,,
6	1 ,,	¼ ,,	3½ ,,	Partial.	24 ,,
7	2 ,, Control.	—	5 ,,	*Nil.*	24 ,,
8	2 ,, ,,	—	5 ,,	,,	24 ,,

The material for these experiments was obtained by centrifugalising menstrual blood from the uterus and vagina. The fluid in the case of the uterus was clear or only faintly stained with hæmoglobin; that from the vagina, on the other hand, was always dark red in colour due to an extreme degree of hæmolysis In the case of those experiments where complete resolution of clot occurred the fluid was again centrifugalised and the supernatant liquid mixed with fresh normal blood and incubated at body temperature. The results of this further series are shown in Table V.

TABLE V.—*To show Thrombolytic Power in Menstrual Fluid after Thrombolysis has occurred Fluid again Centrifugalised.*

Experiment	Venous blood	Menstrual blood	Coagulation time	Clot resolved	Time
1	1 c c	2 c c	4 min	Partial	24 hours
2	1 "	1 "	3	"	"
3	1 "	1 "	4 "	*Nil*	"
4	1 "	½ "	4½ "	"	"
5	1 "	¼ "	5 "	"	"
6	1 "	—	4 "	"	"
7	2 " Control	—	5 "	"	"

It appears, therefore, that the body producing thrombolysis is present in the fluid portion of the menstrual discharge, and, moreover, acts in a quantitative manner, since it will not produce the resolution of an unlimited amount of thrombus Its power becomes gradually less in material obtained by repeated autolysis and centrifugalisation Furthermore, the fibrinolysin present in the menstrual discharge appears to be specific, since it does not exert any very evident action upon fibrin obtained in the usual manner from ox blood as shown in the following series of observations (Table VI.).

TABLE VI—*To show Fibrinolytic Power of Menstrual Blood upon Ox Fibrin.*

Experiment	Menstrual blood	Source	Fibrin dissolved	Time
1	4 c c	Vagina	? Partial	24 hours
2	3 "	"	"	"
3	2 "	"	*Nil*	"
4	1 "	Uterus	"	"
5	½ "	"	"	"
6	½ "	"	"	"

In these experiments a single thread of fibrin was employed, and in only two was there any evidence of solution. In these the fluid after incubation became very tenacious and tarry, resembling the contents of hæmatocolpos both in consistency and colour. The fibrin thread, however, only partially disappeared, and therefore the experiments cannot be considered conclusive. Digestion of ox blood fibrin with varying quantities of other fluids, for example, extract of endometrium, extract of ovary, hydrocele fluid, and fluid from parovarian and pseudo mucinous cysts, also all proved negative The question naturally arises as to whether the thrombolytic property of menstrual fluid is due to any of the known constituents of the latter Blair Bell has shown that calcium salts are present in the menstrual discharge in excess of those present in the circulating blood The fluid also contains mucin secreted by the cervical glands and small quantities of lactic and butyric acids The results obtained in a series of experiments undertaken to ascertain the effect of these substances upon the coagulation time of blood and the possession of any thrombolytic power are shown in Table VII.

Since observing the phenomenon of thrombolysis in menstrual blood I have investigated several pathological fluids from the same standpoint I do not wish to go into detail on the present occasion, but in passing I may say that from material obtained from various ovarian cystomata the fluid which appears to possess the best marked thrombolytic power is that contained in lutein cysts. This is interesting in view of the supposed lutein origin of ovarian blood cysts, and the observation that I have already noted as to the absence of fibrin and fibrinogen from the contents of such cysts. It is probable that thrombolysins play an important part in the living organism in removing products of diffuse hæmorrhage and thrombosis. A body of this nature certainly appears to occupy a definite rôle in the physiology of menstruation by rapidly and easily removing the results of intra-uterine coagulation.

Summarising, therefore, the preceding facts, it appears necessary for descriptive purposes to classify the menstrual discharge under two headings—viz., (1) contents of the uterus; and (2) contents of the vagina. The former consist of thrombus containing epithelial cells, leucocytes, and calcium salts, mixed with the secretion from the uterine glands containing fibrinolysin. The fluid is alkaline in reaction and gives the spectrum of oxyhæmoglobin. The contents of the vagina consist of the products of thrombolytic and hæmolytic digestion, mixed with vaginal cells and the secretions of the corporeal and cervical glands. A considerable amount of mucus is present with traces of lactic and butyric acids. The fluid possesses a faint but distinct odour, and is alkaline in reaction. In colour it is dark red and gives the spectrum of oxyhæmoglobin. Micro-organisms abound in the fluid contained in the vagina, but are rare in material obtained from the uterine cavity.

The Influence of Thrombokinase in Promoting the Clotting of Menstrual Blood.

Rapid clotting of the blood in the tissues of the endometrium is undoubtedly facilitated by the thrombokinitic power of the endometrial stroma. In the results of experiments detailed in Tables I. and III. it was shown that both the tissue of the endometrium and menstrual blood have the power of diminishing the coagulation time of normal blood. This phenomenon I attribute to an excess of thrombokinase derived from the stroma cells. In the results contained in Table VII. I have shown that rapid clotting is not aided by any of the known constituents of the menstrual fluid in such proportions as occur in the latter. On the other hand, it is well known that extracts of certain tissues, such as the testis, have the power of lowering the coagulation time of blood. In the case of the uterine endometrium this specialisation of function and storage of thrombokinase subserves a very important physiological purpose. It must be remembered that under normal conditions hæmorrhage from the menstruating endometrium is a slow ooze, and there is ample time for the blood to be brought into relation both with the stroma cells which contain the thrombotic elements, and the secretion of the uterine glands which brings about thrombolysis. The high thrombokinitic power of the endometrium is therefore a provision of nature to facilitate clotting and prevent excessive hæmorrhage. Even in well-marked cases of hæmophilia profuse uterine hæmorrhage very rarely occurs during menstruation, as recorded by Gulland and Goodall. This to my mind is a very strong clinical argument in favour of the views that I have just put forward.

Thrombokinitic power of the endometrium is present both in the non-menstruating and menstruating uterus, but appears to be most marked in the latter. Clinically the phenomenon is often evident during the operation of curetting. It is well known how rapidly the blood clots when mixed with the curetted endometrium, and special precautions are necessary to obtain tissue for microscopical purposes unmixed with clot. If, now, the curettings are incubated at body temperature partial or complete thrombolysis occurs according to the proportion of tissue and thrombus present. When curettage is performed during a menstrual period thrombolysis appears to be much more active.

The Histological Characters of the Menstruating Endometrium.

Considerable attention has been given within recent years to the anatomical study of the endometrium in the human female, both during the state of rest and during the phases of actual menstruation. Young, in 1911, pointed out that the stroma of the endometrium is to be regarded as a sponge-like structure formed by the union of branching processes from the individual cells, and he suggested that the extravasation of blood into the intercellular spaces is due to metabolic changes taking place within the cells, initiated in all probability by the stimulus of a hormone of ovarian origin. Since the appearance of Young's work I have examined numerous sections of endometrium obtained by operation, and have satisfied myself that his views as regards the development of a reticulum from the cells of the endometrial stroma are correct. Details in structure are best seen during the early pre-menstrual stage before hæmorrhage occurs into the stroma. The individual cells at this period are widely separated from each other, as shown by Fig. 3, and the identity of the so-called reticulum with the branching processes of the individual stroma cells is quite evident.

More recently, Adler and Hitschmann have described in detail the histological characters of the endometrium during the complete menstrual cycle. They point out that the cycle is divided into three stages—viz., pre-menstrual, menstrual, and post-menstrual—the essential changes affecting both the glandular and stroma elements in the endometrium. During the menstrual flow there is a definite loss of epithelium both from the glands and surface of the endometrium. After menstruation an extraordinary formation of new cells occurs, correlating to the amount of tissue lost. This continues until the end of the interval before the succeeding menstruation, when the newly formed epithelium is anatomically complete.

DESCRIPTIONS OF ILLUSTRATIVE PLATES.

The references to Figs. 7 to 13 will appear in the concluding portion of the Lecture.

FIG. 2.—Tissue of endometrium contained in normal menstrual blood (second day), and showing surface epithelium, glands, and stroma cells. The photograph proves that disintegration of tissue normally occurs and that a breach of surface exists.

FIG. 3.—Stroma of endometrium under high magnification to show branching processes of stroma cells and formation of a reticulum.

FIG. 4.—Normal diffuse hypertrophy of endometrium (superficial portion). Superficial glands irregular and dilated; deep glands do not take part in the premenstrual hypertrophy.

FIG. 5.—Early premenstrual decidual change in superficial cells of stroma of endometrium. Note branching of cells and large nuclei.

FIG. 6.—Well-marked "decidual" change in stroma cells during normal menstruation. Section taken from surface of endometrium.

FIG. 7.—Hydrometra in rabbit. Activity of uterine glands. Note dilatation of glands.

FIG. 8.—Hydrometra in rabbit after double oöphorectomy. Shows atrophy of endometrium.

FIG. 9.—Atrophied endometrium in case of diffuse fibrosis uteri. Hæmorrhage was profuse and necessitated hysterectomy.

FIG. 10.—Endometrium showing dilatation of glands and hæmorrhage into stroma. Condition resembles premenstrual stage of normal endometrium.

FIG. 11.—Endometrium, active. Glands large and cystic; leucocytes and epithelial débris in lumina; stroma infiltrated with red blood cells.

FIG. 12.—Endometrium during rest. Glands small and collapsed.

FIG. 13.—True infective endometritis. Note large thrombosed capillaries. Hæmorrhage was not a clinical feature in this case.

Physiological function is then developed, as shown by the production of secretion in the glands. At this stage they are large and dilated, with intraglandular processes composed of high columnar secreting epithelium. At the termination of the function, on the other hand, the glands are small, narrow, and long, and the epithelium low.

The appearance exhibited by glands during the pre-menstrual stage is shown in Fig. 4. It is important to note that apparently only the superficial portion of the endometrium takes part in the active changes during the acme of the cycle. The stroma in relation to the metrium, although congested, does not exhibit under normal conditions the same œdema and hæmorrhage as the superficial layer. It appears, therefore, to act as a rearguard, whose duty it is to replace the tissue lost during the destructive stage. The superficial stroma cells of the endometrium hypertrophy during the pre-menstrual period, and present a more or less similar appearance to the decidua of an early pregnancy. (Fig. 5.)

Occasionally this "decidual reaction" is extremely marked, as shown in Fig. 6, which represents a portion of the curettings obtained from a single girl, aged 23, the operation being performed for dysmenorrhœa. In this particular instance no question of pregnancy could be entertained. Blair Bell has drawn attention to a similar appearance sometimes noted in the "casts" of the uterus passed by patients the subject of so-called membranous dysmenorrhœa or exfoliative endometritis. The view that I hold is that this disease merely represents an extremely high grade of development of what in a lesser degree is a normal anatomical occurrence, and in a sense may be regarded as an atavistic phenomenon. These "casts" are almost precisely identical with the menstrual clot and complete denudation of the endometrium which is present in the higher apes.

Adler and Hitschmann remark that when the development of the endometrium is completed, if pregnancy does not take place, hæmorrhage occurs simply because the glands in the mucosa throw out their secretion. In other words, the loss of blood indicates the termination of the physiological cycle. This hæmorrhage is associated with shedding of portions of the superficial endometrium, both stroma and glands. That destruction of the tissue definitely occurs is shown by Fig. 2, which represents tissue found in the clot collected from the uterine cavity before cytolysis has taken place. Gland epithelium and stroma cells are quite evident.

The facts, therefore, to which special emphasis should be directed are the following: 1. Physiological enlargement and dilatation of the uterine glands during the pre-menstrual stage. 2. The formation of a modified decidua by the superficial cells of the stroma. This, as a rule, is only partial. 3. Hæmorrhage following the complete development of the endometrium associated with partial disintegration of the superficial layers of both glandular epithelium and stroma. 4. A period of regeneration dating from the stage of post-menstrual destruction to the development of a new layer of secreting epithelium and fresh decidua. Correlating these facts with the statements already made upon the biochemical function of the endometrium, I would observe that under physiological conditions hæmorrhage does not occur until both stroma and glands are at their highest grade of development; in other words, both factors are present and physiologically balanced to control uterine bleeding and dispose of the clot so produced.

Factors in the Production and Cessation of the Menstrual Hæmorrhage.

Before an inquiry can be instituted into the question of pathological bleeding it is a matter of the highest importance to ascertain if possible the machinery concerned in the control of normal menstrual hæmorrhage. Three factors suggest themselves as having a possible influence upon such a question—viz., (1) The effect of uterine muscular contractions in limiting the supply of blood flowing to the endometrium; (2) the action of a hormone or hormones producing capillary dilatation in utero; and (3) the biochemical function of the endometrium itself.

As regards the first named, it has been stated that such contractions are present, and that if the uterus is palpated during the progress of the menstrual flow it is not infrequent to note periodic variations in its consistency. Direct demonstration of this fact is of course difficult in the human subject, but in the case of rabbits Blair Bell has recorded that extreme uterine contractions are produced by the injection of uterine secretion. I have also observed the occurrence of direct peristaltic movements in the uteri of rabbits when the secretion obtained from an artificial hydrometra is administered intravenously. Is it possible, therefore, that a portion of the uterine secretion is reabsorbed and serves as a direct stimulus to uterine contraction, thus diminishing the amount of blood flowing to the endometrium?

Bond has gone very carefully into the chemical composition of the uterine secretion in rabbits obtained from an artificial hydrometra. He found that the fluid was clear and watery in appearance with a low specific gravity, and that it held a large quantity of sodium chloride in solution. During pregnancy this secretion was absent. Also, in those animals where the uterine cornua were ligated Bond noted that the period of œstrum was prolonged and occurred frequently. I am at present carrying out an investigation in rabbits into the physiological properties of the uterine secretion obtained by Bond's method, with a view to ascertaining the effect, if any, of this secretion upon the production of œstrum and the control of hæmorrhage. The results so far obtained are sufficiently interesting to place before you.

Experiment I.—Virgin rabbit, weight 1570 grm. On Dec. 9th, 1913, both uterine cornua were ligated and a third ligature passed around the upper end of the vagina. The wound healed in a few days, and on Dec. 19th the animal was placed with the buck. Coitus occurred almost daily until Jan. 12th, when the animal was killed Both uteri were distended and 3 c c. of fluid were collected under aseptic precautions. The pelvic viscera and vagina were much congested and the animal was evidently experiencing œstrum. The activity of the uterine glands is shown well in Fig. 7, representing a section through the uterus of this animal compared with Fig. 8, showing a section through the uterus of an animal during the period of anœstrum.

Of the uterine secretion 1 c.c. was immediately mixed with 1 c.c. of the animal's blood. Clotting was complete in 1½ minutes. The control clotted completely in 3½ minutes.

Experiment II.—Mature virgin rabbit, weight 1580 grm. Not "on heat." The animal was inoculated on Jan. 14th, 1914, into the tissues of the thigh with 2 c.c of the turbid opalescent uterine secretion obtained from Experiment I. The animal was examined the following day and signs of pro-œstrum were present. The following day the abdomen was opened and the pelvic viscera inspected. The uterus was swollen and congested and evidently in œstrum. One cornu of the organ was excised for microscopical examination, and the other was ligated as in Experiment I. in order to obtain a fresh supply of material.

Experiment III.—Virgin rabbit, weight 1305 grm. On Dec. 12th, 1913, ligation of the right uterine cornu was carried out, the left cornu being left in communication with the vagina. Ten days later the animal was placed with the buck, and it was again noted that coitus occurred at once and almost daily till the date on which it was killed, Jan. 13th, 1914. A well-marked hydrometra of the right uterine cornu was present, and 3 c c. of turbid opalescent fluid were collected with aseptic precautions. 1 c.c. of the fluid was placed with 1 c.c. of blood. Clotting was complete in 2 minutes. The control clotted in 4½ minutes. The left cornu was much congested and in a state of œstrum. No pregnancy was present.

Experiment IV.—Virgin rabbit, weight 1295 grm. On Jan. 14th, 1914, the animal was inoculated into the tissues of the thigh with 1 c.c. of uterine secretion obtained from Experiment III. On the following day an examination did not show any evident sign that the animal was "on heat." On the second day after operation the abdomen was opened and the pelvic organs examined. Congestion of the uterus and vagina was present, but not to the extreme degree found in Experiment II. It appeared that œstrum was commencing and not fully established. One cornu was excised for microscopical examination; the other was ligated in order to obtain a further supply of secretion.

Experiment V.—Virgin rabbit, weight 1950 grm. On Dec. 16th, 1913, double oöphorectomy was performed, with ligation of both uterine cornua at their junction with the vagina. Ten days later the animal appeared in good health and was placed with the buck. Coitus occurred regularly, and in fact no difference was noted between this animal and the two others in which the ovaries had not been removed. The animal was killed on Jan. 12th, 1914. A small hydrometra was discovered in both uterine cornua, but only 1½ c.c. of fluid could be obtained from the same. The pelvic organs were not markedly congested and the uterine secretion had a different appearance to that noted in the two normal animals. It was a clear watery fluid, not turbid, and when added to an equal quantity of rabbit's blood produced no alteration in the coagulation time.

Experiment VI.—Mature virgin rabbit, weight 1320 grm. Not "on heat." On Jan. 14th, 1914, the animal was inoculated into the muscles of the thigh with 1 c.c. of uterine secretion obtained from Experiment V. No point of interest was noted upon the following day, and two days after the inoculation the pelvic organs were inspected through an abdominal incision. They appeared normal and not congested. One uterine cornu was excised for microscopical examination and the endometrium showed no evidence of marked activity, the glands being small and contracted. Double oöphorectomy was performed and the remaining uterine cornu ligated in order to obtain a further supply of material if possible.

The experiments, as far as the investigation has gone, appear to show that the uterine secretion in rabbits, at least, is under the control of the ovaries both as to amount and physiological action. The normal secretion apparently aids coagulation of the blood—a point of interest when it is remembered that pro-œstrum in this animal is not associated as a rule with external hæmorrhage. The secretion also appears to stimulate œstrum. Bond's experiments have shown that when the fluid is pent up, as in artificial hydrometra, œstrum is frequent and prolonged, and my investigations certainly tend to confirm his observations. It appears possible, therefore, that uterine secretion, stimulated and controlled by an ovarian hormone, is partly absorbed and produces that dilatation of vessels which is characteristic of the late stages of pro-œstrum and immediately precedes œstrum. Whether this is the case with the human female it is only possible to surmise, but with the close analogy of menstruation to pro-œstrum it is certainly possible. At the same time, clinical experience has shown that a period of œstrum or sexual desire may occur in the human species quite independently of both uterus and ovaries, as is the case when these organs have been removed singly or together at an early period of married life. The subject is naturally difficult to investigate from a scientific standpoint, and observations are most reliable when based upon animal experiments.

Concerning heterogeneous extracts prepared from the uterine endometrium and from the ovarian stroma and corpus luteum, I have been unable to satisfy myself that these have any effect in stimulating the onset of œstrum or in accelerating menstruation. At my request Messrs. Burroughs and Wellcome kindly prepared for me extracts of uterine endometrium and ovary from tissues obtained from the sheep. A series of rabbits were inoculated daily with these extracts in doses of 1 c.c. for a period of 28 days. At the end of this time the animals were killed and the pelvic organs, suprarenal and thyroid glands, subjected to detailed macroscopical and microscopical examination. The results as regards the uterus and ovaries are shown in Table VIII.

TABLE VIII.—*To show Effect of Extracts of Sheep's Endometrium and Ovary containing Corpus Luteum upon the Uterus and Ovaries of Rabbits.*

Rabbit.	Initial weight.	Weight at death.	Extract.	Uterus.	Ovaries.
1	1730 grm.	2012 grm.	Endometrium.	Normal.	Normal.
*2	1830 ,,	1790 ,,	,,	Large and congested.	Recent corpus luteum.
3	770 ,,	945 ,,	Ovary.	Normal.	Normal.
4	970 ,,	1135 ,,	,,	,,	,,
5	1390 ,,	1500 ,,	Endometrium and ovary.	,,	,,
6	1430 ,,	1425 ,,	,,	,,	,,

* This animal aborted after the eleventh injection. It was not known to be pregnant when the experiment was commenced.

The uterus and ovaries in these six animals, with the exception of Rabbit 2, presented no difference, either to the naked eye or under the microscope, to the same organs of two control animals. All were in an anœstrus condition, showing no congestion and no recently ruptured Graafian follicles. Rabbit 2 cannot be included in the results owing to the fact that it was pregnant when the experiment commenced. I conclude, therefore, that extracts of the endometrium and ovary of the sheep have no physiological effect in stimulating œstrum in the case of the rabbit.

Similar negative results were observed in the case of six women who received intramuscular injections of these extracts during the premenstrual period. No alteration was noted either in the duration of the cycle or length of the actual menstrual period. Whether these results would be modified by extracts prepared from organs during a period of sexual activity it is impossible at present to say. Such extracts are difficult to obtain in quantities sufficient for experimental purposes.

Be this as it may, there is ample evidence available to show that normal pro-œstrum and menstruation are under the control of the ovary and its associated endocrinous glands. It is superfluous on my part to dwell upon this aspect of the subject, which has been so admirably investigated within recent years. In particular, I would refer to the work of Biedl, Blair Bell, and Harvey Cushing. In the light of such knowledge we cannot say that menstruation is dependent solely upon ovarian function, although the latter is undoubtedly the strongest link in the chain. We must recognise the fact that the function of this organ is influenced by other elements in that great endocrinous system. A further reference to this subject will be made when discussing pathological uterine hæmorrhage.

(*To be concluded.*)

ANÆSTHETICS AND DIAGNOSIS.[1]

BY J. BLUMFELD, M.D., B.C. CANTAB.,
SENIOR ANÆSTHETIST TO ST. GEORGE'S HOSPITAL.

ALTHOUGH the commonest use of anæsthetics is to allow of the performance of surgical operations it is not their only use. From the other occasions on which they are employed most interesting results are sometimes forthcoming, and it is with a few of these that I now wish to deal. These less common occasions for the induction of anæsthesia are, first, to permit of complete examination, particularly in abdominal, rectal, and pelvic cases; secondly, to alleviate pain or convulsive attacks; thirdly, to relieve respiratory troubles, as in cases of asthma; and fourthly, to relax muscles so as to get rid of their tone for the time being or to abolish spasm.

In connexion with these comparatively uncommon uses of anæsthesia I have had during the last 15 years some interesting experiences the relation of which may, I think, be not unprofitable. I have seen diagnoses made with confidence beforehand completely changed when the patient was anæsthetised, tumours that had been declared irremovable found to be removable and safely removed, masses revealed the presence of which had been hitherto unsuspected, and operations abandoned when they had been previously held to be perfectly feasible. I have also seen the cause of an existing respiratory trouble revealed in an unexpected direction, and, on the other hand, I have seen respiratory trouble arising in the course of anæsthesia lead to the detection of a mediastinal tumour which had caused no *symptoms* in the *conscious* patient. Thus it appears that the administration of an anæsthetic may sometimes be the chief step in making a correct diagnosis, not merely by allowing of an examination which [illegible] but also by providing fres [illegible] observed behaviour of [illegible] anæsthesia.

First as regards the use of anæsthesia in abdominal examination. I believe it would be a good rule if almost every case of abdominal tumour were examined under an anæsthetic before removal was attempted The examination can always be made with the patient and all accessories prepared, so that if operation is decided on it can be carried out forthwith and the patient saved a second anæsthetic. I am led to this belief in the advisability of examining these cases under an anæsthetic by the frequency with which I have observed that the surgeon finds when he operates that the condition is different from what he had expected as a result of his previous examination with the patient conscious. Sometimes in tumour cases the tumour is not even in the place or concerned with the organ with which he had expected to find it connected. By not knowing this beforehand he opens the abdomen at a disadvantage. Such was the case, for instance, when an abdomen was opened and an appendix removed which proved to be but little concerned in the patient's symptoms, for a fuller examination of the abdomen from within led to the discovery of an early carcinoma of the sigmoid removable, but not through the same incision. This growth would have been felt by a bimanual examination under anæsthesia. In another patient the abdomen was opened for removal of a growth in the abdomen, but so many and such large secondary deposits occupied the epigastric region that removal was out of the question. With the complete relaxation of full narcosis these growths would have been palpable.

Such a discovery in time happened in another interesting case. Captain A, aged 35, a well-made, active soldier, had complained for weeks of vague indisposition associated with pain in the epigastrium and around the ribs. Nothing abnormal could be felt on examination of the abdomen. A small, firm tumour was discovered on the back, and it was decided to excise this in case its nature should throw any light upon the abdominal discomfort. For this purpose an anæsthetic was given. When the patient was fully under the anæsthetic the surgeon examined the abdomen, and through the flaccid walls he easily felt several masses; one in the neighbourhood of the liver felt so superficial as to make him surprised that it had not been easily detected at his previous examination; it was hard and felt as though it was actually in the abdominal parietes.

Again, a woman aged 68 had attacks of abdominal and thoracic pain at varying intervals. They were accompanied by a sense of fulness in the abdomen and by flatulence; the pain was in the right hypochondrium and affected the shoulder on that side. Two days after such attacks she was slightly yellow. The bowels were often constipated, with alternating diarrhœa. There was some general wasting. Examination of the abdomen showed a normal contour except for some bulging in the right loin. Palpation revealed a rounded body approximately in the position of the lower pole of the right kidney. Under the upper segment of the right rectus nothing definite could be felt, but an impulse could be communicated from a hand in this region to that in the iliocostal space. The diagnosis was made of an enlarged gall-bladder. During anæsthesia a definite mass in the transverse colon was made out and secondary masses in the neighbourhood of the liver and pancreas.

Such cases as those that I have related, which are only examples of very many others, are enough to support the view that an examination under full anæsthesia should be made in most abdominal cases before operation, if not in all cases of abdominal tumour.

It is in the abdominal wall, too, that those strange phantom tumours sometimes appear the confident diagnosis of which can be made only by the use of anæsthesia. A tumour of this sort disappears completely with full narcosis, and, moreover, it disappears in a particular way. Sir William Bennett[2] has pointed out that it does not suddenly vanish as though it had slipped away into another part of the abdomen, but it gradually melts away under the hand. Moreover, as the same observer has noted, during light anæsthesia these muscular tumours harden and increase, so that in examining such cases the hand should be kept on the tumour from the beginning, and the behaviour under early and then under late narcosis will show with absolute certainty that the tumour is a phantom one due to muscular contraction.

---

[1] A paper founded on a lecture delivered at the Medical Graduates' College and Polyclinic.

[2] THE LANCET, Jan. 4th, 1902, p. 1.

One good example of phantom tumour, which came under my own notice may be told here. Mrs. B, 54 years old, a pink-faced fattish lady, with a lively manner, but described by her nurses as "very difficult to do anything with," suffered for some days with pain in the abdomen, increasing distension, and complete constipation. The physician and practitioner in charge thought that probably it would be necessary to open the cæcum, and that certainly the patient could not go another night in her present condition. When the surgeon and I arrived the abdomen was greatly distended, apparently with a large tumour rising from below and occupying all the mid-portion of the abdomen. In the semi-recumbent position, in which alone she could breathe with any comfort, an anæsthetic was given slowly and inhaled with no difficulty. As soon as anæsthesia was established the tumour completely disappeared. Some gurgling was heard at this time. Very thorough examination by the three medical men revealed no evidence of any tumour whatever within the abdomen.

These phantom tumours occur elsewhere than in the abdomen and are easily mistaken for growths. When such is the case and the patient is prepared for operation it is very striking when the dressings are removed after anæsthesia is induced to find no tumour present on which to operate. In the case of the abdomen, apart from these phantom tumours which disappear altogether, there is the interesting protective rigidity of muscle which must be considered in connexion with anæsthesia and diagnosis; for I have seen a correct diagnosis made absolutely by noticing the behaviour of a rigid portion of rectus under anæsthesia. The rigidity of the abdominal wall in cases of acute disease, as, for instance, appendicitis, is of course familiar to all, and is an important element in making the diagnosis. This protective rigidity, however, in acute cases usually disappears entirely when the patient is fully under the anæsthetic. Now, in a chronic case there may be such a rigidity which does not disappear in the same way. In the case to which I am referring there was a somewhat vague history of long-standing abdominal pain; the abdomen could not be easily palpated because almost everywhere the wall was kept rigid. Under an anæsthetic this rigidity all disappeared—and here is the important point—except in the upper part of the right rectus; this portion of muscle was tight and rigid, whilst the rest of the abdomen was relaxed and moving. Noticing this fact, the surgeon felt convinced of underlying disease, opened the abdomen in the neighbourhood, and found a chronic duodenal ulcer which had evidently perforated long since and had been shut off by inflammatory products which had affected the under surface of the anterior abdominal wall. It may be noted, by the way, that it is in such a case as this that the anæsthetist may find it impossible to get a condition of the abdominal wall which is comfortable for the operator. I believe in some of these long-standing cases there is a condition of contraction of the muscular fibres which no anæsthetic will overcome; perhaps after long-continued reflex protective contraction some fibrotic change has come about, and the muscle can no longer relax.

Here is another case which brings out the value of examination under an anæsthetic, and is a good example of a large class. A healthy married woman, aged 40, rather nervous, not stout, complained of an abdominal swelling which gave pain and of three months' amenorrhœa. On abdominal and vaginal examination the diagnosis was made of a three months' pregnancy together with a tumour which was probably an ovarian cyst. The enlarged uterus was on the left and the cyst on the right of the whole abdominal swelling. There was some contraction of the abdominal walls which made the examination not absolutely satisfactory, and the gynæcologist decided upon re-examining under anæsthesia before operating for removal of the cyst. This time, on making a combined vaginal and abdominal examination with completely relaxed abdomen, he found that the enlarged uterus constituted the right hand part of the tumour, and that on the left was a firm mass almost certainly fibroid. Irregular contractions in both parts of the mass probably led to the mistaken diagnosis, and this was only remediable by the examination during anæsthesia; the altered diagnosis led to postponement of the operation and normal full-time labour.

Another gynæcological case of different character where there was no tumour, but where the behaviour under an anæsthetic clinched the diagnosis, may be told here. Mrs. C, a dark, thin, highly neurotic married woman, aged 35, had had the appendix removed five years previously; three years later the abdomen had been opened again on account of persistent pain thought to be due perhaps to adhesions in connexion with the previous operation. Two years later she still suffered from chronic pain in the right side of the lower abdomen and pelvis. On vaginal examination it was found that the pain was removed when the cervix uteri was pressed up; any instrument, however, to keep the uterus up itself caused so much pain that it could not be borne. It was then decided to make a thorough examination during anæsthesia, as it was not obvious from the position of the uterus or from anything else why the pain should be present or should be relieved by pressing up the cervix. By palpating the fully relaxed abdomen nothing abnormal could be detected, but when examination was made per vaginam the interesting fact was revealed that pressure at a certain point in Douglas's pouch gave rise to reflex alteration of the breathing; there was some laryngeal spasm with straining of the abdominal wall. The reflex was produced in no other way. In order to test the reality of this phenomenon some traction was exerted upon the uterus, a procedure which will itself often provoke reflex inspiratory spasm, but no result followed upon this traction nor upon stretching the vagina; yet again directly the particular spot in Douglas's pouch was pressed upon there was reflex spasm. This repeated experience made it obvious that something was present to account for this peculiar local susceptibility, and closer examination revealed the presence of a band dragging on the cervix at the point where pressure gave the pain in the conscious patient.

Such instances as the following show the irretrievable disaster of not examining when symptoms suggest its advisability, and in this case, as in many others, the desirability not merely of examining, but of examining during anæsthesia, is shown. A lady, aged 50, highly intelligent, but modest and nervous, suffered from pain in the lower abdomen and occasional passage of blood and mucus from the rectum. At some times she was much better than at others, often feeling quite well and having no discharge from the bowel. She resented the idea of any local examination and was allowed to drift on with medical treatment for "*colitis*," as her symptoms had now been christened. Nearly 18 months after the first symptoms she was induced to submit to an examination under anæsthesia. A large ulcerating carcinoma at the recto-sigmoidal junction was easily discovered. *It could not, in the surgeon's opinion, have been reached by the finger unless the patient was under an anæsthetic.* The growth was by this time inoperable and a palliative colotomy was all that could be offered, whereas a year ago probably the growth could have been seen with a sigmoidoscope, even if not at that time actually felt, and a complete removal effected.

Harley-street, W.

ON OPERATIONS FOR HÆMORRHOIDS: A REVIEW OF 850 CASES.

By ARTHUR NEVE, F.R.C.S. EDIN.,
SURGEON TO THE KASHMIR MISSION HOSPITAL.

HÆMORRHOIDS are common in North India, and not less so in Kashmir, where very severe forms are also met with in all sorts and conditions of men. As might be expected in a population living chiefly upon rice and vegetables constipation is a general habit; piles occur and are neglected, leading to inflammatory protrusions, severe hæmorrhages, anæmia, and other complications. The value of surgery is recognised, but the district which feeds the hospital is half the size of England, and men come 10 or 14 days' journey, sometimes in a very debilitated condition. The patients have included Sikhs, Pathans, and Tibetans, as well as a majority of Kashmiris, and a very few Europeans. No women are included in the series.

Preliminary treatment.—In some mild cases we have relieved the patient without operation by means of a regulated diet, suitable laxative medicine, and a suppository containing 5 per cent. chrysarobin with belladonna. Occasionally very weak old men are kept under treatment for a few days, especially if they suffer from any cardiac or other organic disease, but in the whole period only one patient was finally refused the benefit of an operation.

Methods of operation.—The method of choice in this hospital has long been that of clamp and cautery; and though there have been some few cases of ligature or of Whitehead's operation which we specially tried from 1893 to 1897, yet I several times regretted my temporary separation from the trusty clamp. Many other surgeons have made their early experience in this hospital, such as Holland of Quetta, Lechmere Taylor, Clark, and Gaster of North India, and each has carried a Kashmir clamp to his subseqent sphere, and considered it his method of choice.

H. Stone[1] reviews the method of the Johns Hopkins Hospital for a period of 20 years, 470 cases by the Whitehead method, without any death. He quotes W. Graeme Anderson,[2] with 300 cases of which 150 were by ligature, 100 by the Whitehead method, and 50 by clamp and cautery. Anderson preferred the last. O'Conor[3] records 490 ca the Whitehead method. Hadda publishes a based on 223 cases with one death. From Stone's paper I judge that the death-rate is practically negligible in most large clinics. As regards our own experience the results are as follows: Total operations (20 years), 855; known recurrences, 5; improved, 10; not improved, *nil;* left hospital unknown result, *nil;* died, 1.

Comparing the three chief methods of operations I consider that the clamp is suited for all cases, but that the very slight and pedunculated cases are as well treated by ligature, excision and suture. Our experience of Whitehead's method is limited to 20 cases. I have no use for it. It is obviously only needed in the more severe cases with piles all round the circle. In our last 500 cases, many very severe and affecting the whole pile-bearing area, I have failed to see one which could not be adequately treated by the clamp and cautery. In my own experience of excision of the whole area all the stitches were cut out in one case, leaving a raw granulating anus for weeks; in other hospitals I have seen two similar cases and have heard of others. Harvey Stone mentions the following complications in the Johns Hopkins series: (*a*) infected hæmatoma, 1; (*b*) post-operative hæmorrhage, 4; (*c*) local abscesses, 7; (*d*) granulating surface of greater or less extent, 116 cases; (*e*) catheterisation seems to have been very frequently needed; certainly in 1 in 4. As regards ligature, in severe cases it is not easy to apply. If combined with excision there may be troublesome oozing. I saw in my early experience several cases in which great pain was felt. There is a liability to small stitch abscesses, which may leave lingering sinuses.

Details of the operation.—The clamp we use is Benham's, usually called Pollock's, modified in 1882 by Dr. Downes and myself. As Jacobson remarks: "That surgeon will have the best results who has thoroughly familiarised himself with the details of one operation." There are certain errors into which inexperienced operators are apt to fall in using the clamp which show the importance of each of the following details: 1. The anus should be very thoroughly dilated, and this should occupy at least four minutes by the clock. Not merely is this important to obtain a good view and a good prolapse of internal piles, but also to obviate subsequent reflex spasm affecting the urethra and demanding the catheter. In about 10 per cent. of the total the catheter was used once, on the night of the operation. Subsequently catheterisation has only been needed in two or three cases of the 855. 2. Each pile should be gripped with a suitable catch forceps and drawn down and out by an assistant. Thus from four to six forceps will be at once applied, everting the dilated anus. 3. Beginnning at the top pile, the clamp is applied and screwed very tight. If there are only two or three not bulky piles it is applied with the blades longitudinal to the rectum—gripping high up the pedicle, crushing into a line or strip $1\frac{1}{4}$ inches long, then cutting off with curved scissors, and very thoroughly cauterising with the actual cautery, used almost, but not quite, red hot. The Paquelin cautery is very inferior for this purpose. Two iron or copper cauteries are needed with a bulb the size of a cherry. Each pile should take at least two minutes to crush and burn. 4. After the clamp is released care should be taken *not to drag on the wound* and all at the same time, in producing variations in the amount of dental caries in the school children. The method of "partial correlation" enables us to measure the extent of relationship between two varying phenomena, when other *interacting* phenomena are kept constant throughout the series of observations. Thus, it is possible by means of a partial correlation to estimate the relation between the *nature of the* water-supply and the amount of dental caries for a *constant infantile* mortality. This has been worked out, and, taking infantile mortality as a measure of environmental conditions, the partial correlation is 0·3454 ± 0·066, indicating that the harder the water the better the teeth.

---

[1] H. Stone: Annals of Surgery, 1913, p. 647.

[2] Anderson: Brit. Med. Jour., 1909, vol. ii., p. 1276.

[3] O'Conor: THE LANCET, 1910, vol. ii., p. 946.

As it was not practicable to obtain for the districts under consideration the death-rates of children of the same age as those whose teeth were examined, another indirect index of the physique of the children was taken—namely, the general death-rate. This was correlated in turn with the total hardness of water *and with the percentages of* children having four or more carious teeth, the results being given in Table D.

TABLE D.

Variates.	Number of observations.	Correlations.	Probable error.	Remarks.
General death-rate and total hardness of water.	72	0·2965	± 0·06	The lower the general death-rate the harder the water.
General death-rate and percentage of children having 4 or more carious teeth.	72	0·3178	± 0 06	The lower the general death-rate the better the teeth.

Here again there is an apparent, though less marked, association between the nature of the water-supply, the amount of dental caries, and the general death-rate. In a manner similar to the former, the relation between the *nature* of the water-supply and the amount of dental caries can be worked out for a *constant general death-rate*. In this case, taking the general death-rate as a measure of environmental conditions, the partial correlation is 0·4152 ± 0·066, indicating that the harder the water the better the teeth. This result, again, suggests an association between the nature of the water-supply and the condition of the teeth, hard water going with good teeth and *vice versa*.

The returns for the Yorkshire and Lancashire towns were next separated from those for the rest of England and Wales, and the figures for the nature of the water-supply and the amount of dental caries for the two groups were correlated separately. The results are given in Table E:—

TABLE E.

Variates.	Number of observations.	Correlations.	Probable error.	Remarks.
Total hardness of water and the percentage of school children with four or more carious teeth, Lancashire and Yorkshire towns only.	23	0 427	± 0·11	The harder the water the better the teeth.
Total hardness of water and the percentage of school children with four or more carious teeth, rest of England and Wales.	56	0 408	± 0·08	The harder the water the better the teeth.

So far as these figures go they agree with the results given in Table A and indicate that, assuming the social conditions in the industrial districts of Yorkshire and Lancashire to be less favourable for *young children* than in the rest of England and Wales, there is no evidence to show that such *unfavourable surroundings* have any *influence* upon the relationship between the hardness of water and the amount of dental caries amongst the school children.

It is well known that where people are crowded together certain unfavourable conditions are produced which injuriously affect the health of infants and young children. The consequences and concomitants of such aggregation produce the high infantile mortality of our manufacturing towns and *other thickly populated* areas. As another indirect measure of the social conditions in the districts under consideration the figures relating to overcrowding were taken from the General Census Report, and, in turn, correlated with the hardness of water and the percentage of carious teeth in *each of the areas. The results are given in* Table F:—

TABLE F.

Variates.	Number of observations.	Correlations.	Remarks.
Number of persons per house, and the total hardness of the water.	79	0·0526	Not significant.
Number of persons per house, and the percentage of children having four or more carious teeth.	79	0 0672	Not significant.

It will be noted that in this table the correlations are calculated from 79 observations only. This is due to the fact that Aldershot, with its excessive aggregation of soldiers per house, so vitiated the value of the figures that it was omitted. There appears to be no association between the number of persons per house and the hardness of water or between the number of persons per house and the percentage of dental caries.

The partial correlation was next worked out for the relation between the hardness of water and the percentage of dental caries for a constant amount of *overcrowding*, Aldershot being excluded. In this case, taking a constant amount of overcrowding as a measure of environmental conditions, the partial correlation is 0·4643 ± 0·059; the harder the water the better the teeth. This result is noteworthy on *account of its close approximation to the correlation* between hardness of water and percentage of dental caries given in Table A. An attempt was also made to work out correlations in respect of rickets amongst the school children, but owing to paucity of data the results were not significant.

Conclusions.—1. The foregoing correlations and partial correlations indicate an association between excessive softness of water and an increased amount of dental caries amongst the school children, and obversely. 2. The association is evident, but it must be remembered that this inquiry deals only with urban districts; had *it* been possible to obtain reliable returns from rural districts its value would have been considerably enhanced. 3. The environmental conditions, so far as it was possible to measure them, do not seem to be a source of the relation between the hardness of water and the *amount of dental* caries. 4. It must be definitely and *distinctly* emphasised that these correlations and partial correlations merely call attention to an association between the nature of the drinking water and the amount of dental caries, and must not be regarded as necessarily indicating cause and effect. 5. There may well be other factors at work which have a greater influence, but if this investigation merely draws attention to a hitherto neglected topic it will not have been undertaken in vain.

Isleworth.

A CASE OF MALARIAL COMA LASTING 46 HOURS: RECOVERY.

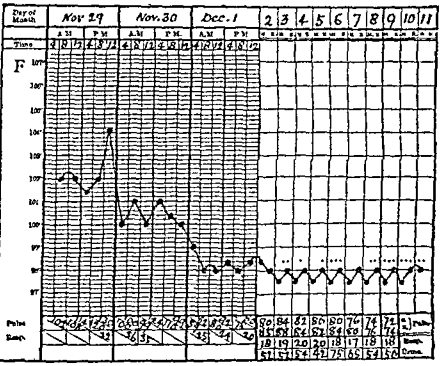
BY A. G. TRESIDDER, M.D., B.S. LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE.

THE following case is perhaps worthy of publication in the columns of THE LANCET, since recovery in a case of such long duration is exceptional, especially in an adult patient.

A. B., aged 23, a gunner serving in the Punjab, was admitted to hospital under my care on Nov. 29th, 1913. He was transferred from camp by Captain A. G. Jones, R.A.M.C., who informed me that the illness began whilst on manœuvres. He had been suffering from fever about three weeks previously, for which he was treated in hospital. He recovered from this and proceeded on manœuvres, during which time he was receiving quinine daily. Early in the morning of the 29th, however, his comrades found him lying in his tent quite unconscious.

When I first saw the patient he had been unconscious for four and a half hours. On examination he was found to be in a condition of coma, with pupils widely dilated but which reacted directly and consensually to light. There were no signs of ocular paresis. The knee-jerks and plantar reflexes were both normal. All the limbs were stiff and rigid. His breathing was stertorous. The temperature was 102° F.; the pulse was regular and full, and its rate 104 per minute. There was incontinence of urine and no specimen was available for examination. There was no evidence of any injury to the skull and no localising symptoms of cerebral hæmorrhage, and there was no smell of alcohol. The heart was normal, as also were the lungs. Captain J. W. H. Babington, I.M.S., reported that the fundi oculorum were quite normal except for slight venous dilatation and the presence of some fine dark pigment on the surface of both discs. A blood slide taken immediately on admission showed no malarial parasites, but with the history of fever before the onset of coma the case was considered to be one of malignant malaria. An intramuscular injection of 10 grains of quinine hydrochloride was given at once, and this was followed after an interval of one hour by 5 grains of the same drug in a pint of normal saline *viâ* the median basilic vein. Later calomel and pulv. jalapæ co. were given by the mouth. During the day the patient sweated freely, and he was sponged several times. Ten hours after admission a second intramuscular injection of 10 grains of quinine hydrochloride was administered.

Nov. 30th.—A slight improvement was evident. The pupils were less widely dilated and reacted well to light, and instead of the eyelids being open and the eyes staring straight above the patient the former were closed and any attempt to open them was resisted. There was still incontinence of urine, and as the bowels had not acted an enema of soap and water was given, but this was retained. At 2.30 P.M. a convulsion occurred; when I saw the patient shortly afterwards he was very cyanosed, his pulse was quick, and his breathing rapid and stertorous. A hypodermic injection of strychnine was given and a pint of normal salt solution administered per rectum. After 30 minutes the colour improved and the breathing became less stertorous. During the afternoon and evening the patient had seven more convulsive seizures; his condition was now very serious and there appeared to be little hope of recovery. These convulsions involved the whole body and they closely resembled the clonic stage of epilepsy. The tongue was bitten during the fits. Later the bowels were well opened, and a small quantity of urine which was secured showed the presence of a trace of albumin. At 10.30 P.M. the breathing was easy and regular; the pupils were contracted to 3 mm. and reacted well to light. Two intramuscular injections of 10 grains of quinine were given during the day, and a total of three pints of saline given per rectum was retained.



Temperature chart.

Dec. 1st.—The rectal salines were continued every three hours during the night. At 2 A.M. some confused sentences were uttered, and two hours later he asked quite sensibly for a drink. At 9 A.M. he was able in a semi dazed manner to reply to my questions. The pupils were normal, as was also the temperature. The pulse-rate was 88 per minute. 10-grain quinine injections twice a day and the salines per rectum were continued. Urine examination: Cloudy, yellow colour; specific gravity 1016; acid reaction, albumin 1/10, no sugar. Microscopic examination of a brownish deposit showed the presence of urates only; there were no casts and no blood cells.

Dec. 2nd.—The patient was now able to take fluid nourishment, and the salines were therefore discontinued. The urine was as previously noted except that the amount of albumin was less. The patient became very restless; he was continually trying to remove the dressings from his arm, and he had to be forcibly restrained from getting out of bed. He also manifested marked delusions of persecution. Potassium bromide 20 grains and chloral hydrate 10 grains, followed by a subcutaneous injection of ¼ grain morphia, were unsuccessful in producing sleep. One injection, 10 grains, of quinine was given.

Dec. 3rd.—The patient's mental condition remained the same, and he suspected that his food was being poisoned. A potassium bromide and tincture of hyoscyamus mixture was given four-hourly during the day, and at night 1/100 grain of hyoscine was administered hypodermically, but no sleep resulted, the patient being restless and talking incoherently all night. Quinine 10 grains three times a day by the mouth was substituted for the intramuscular injections. The urine showed only a trace of albumin, specific gravity 1015.

Dec. 4th.—Magnesium sulphate was given with good result. Up to now no sleep had been obtained since the patient had recovered consciousness. At bedtime $\frac{1}{4}$ grain of morphia was injected subcutaneously, and this was followed by sleep for six hours. But as the delirium continued 30 grains of trional were given by the mouth. This was followed by natural sleep practically up to the evening of Dec. 6th, the patient only waking up for his meals and to pass urine, &c., on which occasions he talked quite sensibly. Dec. 5th.—Quinine was now stopped. The urine was normal in all respects. Dec. 7th.—The patient was now in a satisfactory condition and his mental state quite normal. An uneventful recovery ensued.

Although the diagnosis of this case was not confirmed by the blood examination it seems to me that there can be no doubt that this was a case of malignant malaria. The fact that he had been well dosed with quinine before I saw him would account for the absence of parasites from the peripheral blood. The possibility of the case being one of uræmia is, I think, fairly negatived by the following facts: (1) The daily quantity of urine passed was normal; (2) the albumin only amounted to a trace, which disappeared with the subsidence of the fever; (3) no examination revealed the presence of casts; (4) no history of any etiological factors of nephritis could be obtained; and (5) the administration of quinine in full doses resulted in a complete cure.

The essential pathology of this condition has been conclusively proved to be due to the blocking of the small cerebral vessels with parasite-laden corpuscles. Our object in treatment must therefore be: (1) to destroy the parasites; and (2) to flush them out of the blocked capillaries. In my opinion these cases should therefore be treated energetically and persistently with quinine, commencing with an intravenous injection of 5 to 10 grains of the bihydrochloride in a pint of saline, and subsequently giving intramuscular injections of the same drug in 10 grain doses twice a day until consciousness is restored. The administration of salines intravenously and per rectum will accomplish the second object.

One must not, however, be satisfied with the disappearance of the acute symptoms and the apparent restoration to normal health, for the liability of malignant malaria to recur even after return to temperate climates and after long intervals is a well-known clinical fact. Some even doubt whether malignant malaria can ever be cured, but I think one is hardly justified in taking such an extreme view. Five grains of quinine in tabloid form should be taken every other day for a period of at least three months, and I think if this line of treatment is conscientiously carried out few cases would recur. In the event of the slightest recurrence resort should be at once taken to the intramuscular method of treatment, which is of especial value in combating this form of malaria. I have never seen any harm result from injections of quinine, and I believe that there is no risk of tetanus supervening, provided the injection is made under strict aseptic conditions.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Specimens.—Case of Chorion Epithelioma.—Cæsarean Section under Spinal Anæsthesia in Pregnancy Complicated with Morbus Cordis.—Abdominal Operation After Colostomy for Superior Recto-vaginal Fistula.

A MEETING of this section was held on March 5th, Dr. W. S. A. GRIFFITH being in the chair.

Dr. J. A. BRAXTON HICKS showed for Dr. T. G. STEVENS a specimen of decidual cast passed during the puerperium from the unimpregnated horn of a didelphic uterus. The clinical notes of this case were read at the meeting of this section on Feb. 5th, 1914.[1] The cast, which measured 8 cm. by 6·5 cm. and was 1·5 cm. thick, presented the appearances of an ectopic gestation cast, but was much larger. Microscopically it consisted of fine connective tissue in which were decidual and interglandular cells and the remains of uterine glands.

Dr. CUTHBERT LOCKYER showed a case of Multiple Fibroids removed during the sixth month of pregnancy, in which spontaneous labour occurred at term, followed by a normal puerperium. As the patient was 41 years of age and had never been pregnant, pregnancy was not at first suspected, and treatment for a reddish-brown discharge was carried out for three months in the out-department of Charing Cross Hospital. In October, 1913, a fibroid was impacted in the pelvis, elevating the cervix so that the external os was at the level of the upper limit of the symphysis pubis, and there was an elastic swelling reaching for three fingers'-breadth above the umbilicus. There was secretion in the breasts. On Oct. 24th a fibroid the size of a fœtal head was enucleated from the lower uterine segment, and one the size of a tangerine orange was removed from the back of the uterus higher up. After four months' comparative comfort a healthy female child was born at Charing Cross Hospital.—The PRESIDENT, Dr. WALTER W. H. TATE, Dr. A. E. GILES, and Mrs. SCHARLIEB discussed the case.

Mr. VICTOR BONNEY showed: (1) A Dermoid Cyst of ovarian origin, expelled through the rectum during labour; (2) a specimen removed by operation consisting of the uterus, vagina, and urethra, showing a squamous-celled carcinoma of the cervix co-existent with an adeno-carcinoma of the body of the uterus (a metastatic squamous-celled growth round the urethra was also present); and (3) a Hernia of the Umbilical Cord containing a large portion of intestine which had unwittingly been removed by a practitioner when separating the child at birth. The umbilicus was opened and the cut ends of the gut were united. The child died 12 hours later, and a post-mortem examination showed that practically all the intestine had been removed, the beginning of the jejunum having been joined to the rectum.

Remarks were made by Dr. T. W. EDEN, Dr. H. WILLIAMSON, Dr. G. BLACKER, Dr. BRAXTON HICKS, Dr. R. D. MAXWELL, and Mr. BONNEY replied.

Dr. DRUMMOND MAXWELL showed: 1. A large Interstitial Fibromyoma, 6 inches in diameter in the fundus of the uterus, in a woman aged 23, removed by abdominal hysterectomy after the third stage of labour. It did not complicate delivery, which was spontaneous. Free bleeding ensued after the placenta was expelled. It was found that the placental site occupied part of the capsule of the fibroid, and that it would have been impossible to enucleate the mass without severe mutilation of the uterus. Risks of sepsis were discussed in any expectant treatment, if the tumour had been left *in situ*. 2. Defective Ossification of an Infant's Head. This case exhibited cranial dysostosis, the malformation of the vault of the head being considerable, a large gap existing between the two halves of the frontal bone measuring $3\frac{1}{2}$ by $2\frac{1}{2}$ inches, covered only by tough pericranium. The clavicles were normal. The mother's pelvis showed some contraction, and forceps extraction was necessary. The child died 30 hours after.

Dr. HERBERT WILLIAMSON and Mr. CHARLES NOON contributed a paper on a case of Chorion Epithelioma presenting some unusual features in a woman, aged 39, the mother of two children. After the birth of her last child she was regular for four years. In February, 1912, after three months' amenorrhœa, she passed a vesicular mole. She remained well up to the end of March, 1912, when an abscess was opened per vaginam. She was again better up to July, 1913, when she suffered abdominal pain and vomiting, and began to lose weight. In August there were chest symptoms and slight hæmoptysis. On admission to St. Bartholomew's Hospital on August 4th she was very ill, and there were signs in the left side of the chest. Respirations 40, pulse 108. The skin was jaundiced. There was a large mass in the abdomen extending 7 inches above the top of the symphysis. Per vaginam the cervix was difficult to reach, and a tender, fixed mass occupied the greater part of the pelvic excavation. The question of pregnancy or new growth was difficult. Skiagrams, however, showed dark areas in both lungs, and secondary growth was suspected in the liver. Abderhalden's test by Mr. [illegible] twentieth day after admission. Dr. Williamson showed the mass of growth which occupied the pelvis, and it was remarkable that the uterus itself was little affected, the main portion of the growth being behind the uterus, filling the pelvic cavity and measuring 7 in. by 4 in. It was intimately connected with most of the pelvic viscera, and its lower pole on section exhibited the usual dark-red colour. The liver and lungs contained secondary growths. Sections of the growth and secondary deposits showed typical chorion epithelioma. The value of Abderhalden's test for early diagnosis was pointed out, also the worthlessness of mere exploration of the uterine cavity, seeing that in this case the growth was completely outside the uterine cavity. It was also interesting that 16 months elapsed between the expulsion of the mole and the onset of the symptoms.—Remarks were made by the PRESIDENT, Mr. BONNEY, Dr. S. GORDON LUKER, and Dr. ARCHIBALD LEITCH.

---

[1] THE LANCET, Feb. 28th, 1914, p. 609.

Dr. J. D. BARRIS reported a successful case of the treatment of Pregnancy complicated by Morbus Cordis by means of Cæsarean Section under Spinal Anæsthesia from the maternity department of St. Bartholomew's Hospital; also notes of four other cases which he had collected. Dr. Barris's patient had had ten previous labours, the last in April, 1910. She had rheumatic fever in 1901, also in 1910, just before the birth of her last child. At this time there was no sign of cardiac failure, but she had suffered with shortness of breath since. On admission, under the care of Dr. W. P. Herringham, she was very ill, with a dilated heart, dyspnœa, and an almost uncountable pulse. She improved somewhat by venesection and digitalis, and was transferred to the maternity ward, being then about 27 weeks pregnant. A relapse occurred, and owing to the serious condition Cæsarean section was done (1) because rapid delivery with some form of anæsthesia was necessary; (2) because a general anæsthetic was contra-indicated owing to the condition of the heart. Abdominal Cæsarean section was preferred to vaginal on account of the size of the child, and the patient could be sterilised. The operation was quite successful and the patient made a good recovery. Other cases of this nature were quoted by the author.—Remarks were made by Dr. MAXWELL, Dr. BLACKER, and Dr. FAIRBAIRN, and Dr. BARRIS replied.

Dr. EDEN read a paper on a case of Superior Recto-vaginal Fistula dealt with by an Abdominal Operation after Preliminary Colostomy. The patient was a 6-para, aged 38, who was admitted to the Chelsea Hospital for Women with a large recto-vaginal fistula on July 29th, 1913, about five weeks after the birth of her last child. The fistula admitted two fingers and was situated at the highest part of the posterior vaginal wall. The parts were immobile and the cervix could not be drawn down by traction. It was decided to attack the fistula from above by a transperitoneal operation. Colostomy was first performed by Wallis's method, a loop of the pelvic colon being made use of. Three weeks later the fistula was closed per abdomen. The operation consisted in stripping the uterus and posterior vaginal wall from the rectum down to the level of an inch below the fistula. The rectal aperture was then closed in a transverse plane with interrupted stitches taking up all the coats. There was not room for a second row of so a flap of the posterior vaginal wall was the rectum so as to cover over completel of stitches. The uterus was removed, partly further pregnancy, partly to allow more room for the pelvis. The ovaries were both healthy and the were not removed, and the vagina was left open for drainage. The rectal wound did not heal by primary intention, and after a week a foul vaginal discharge occurred with moderate pyrexia. These unfavourable symptoms soon subsided, and 18 days after the operation the lower segment of the bowel was irrigated from above and found to be watertight. Four weeks after closing the fistula the continuity of the pelvic colon was restored by excising the colostomy opening and re-uniting the gut by end-to-end anastomosis. From this the patient made a good recovery. The author claimed for colostomy certain definite advantages in dealing with bowel fistulæ high up in the vagina: (1) it permitted preparation of the operation area to be carried out; (2) it ensured that the portion of bowel repaired could be kept absolutely at rest during healing; and (3) it prevented re-infection of the operation area from the fæcal stream The steps of the operation performed were illustrated with the epidiascope.—Remarks were made by the PRESIDENT and Dr. GILES.

PATHOLOGICAL SECTION.

Lesions of the Kidney in Ulcerative Endocarditis.—"Eleidoma."

A MEETING of this section was held on March 17th, Dr. F. W. ANDREWES, the President, being in the chair.

Dr. J. F. GASKELL read a paper on the Lesions of the Kidney in Ulcerative Endocarditis. He said that such lesions were of two kinds, though both were attributable to the same mechanical cause—namely, the carriage of particles from the infected valves to the organ. If the particles were large septic infarction occurred; if the particles were small a form of nephritis was brought about due to the lodging of them in glomerular capillaries. Such lesions, in contra-distinction to those of glomerulo-tubular nephritis, in which the whole organ is affected, only affected a variable number of capillaries in a variable number of glomeruli. This form of nephritis had been claimed by Schottmüller, Libman, and others to be diagnostic of the infection of the heart valves by a certain streptococcus which they named streptococcus viridans, a type of infection which usually lasted some considerable time; it was probable, however, that, as Horder and others had shown, this organism was identical with the type of streptococcus found in normal saliva—namely, streptococcus salivarius. Dr. Gaskell's paper also supported the view that embolic focal nephritis was a [illegible] of infection of the heart valve [illegible] ulcerative endocarditis produced by inoculation with streptococcus salivarius from the normal saliva.

Mr. S. G. SHATTOCK described a large tumour under the name "Eleidoma," which had been removed from the back by Sir William Fergusson, and was at present in the museum of the Royal College of Surgeons of England. It belonged to a group of neoplasms first clinically described by Edward Cock, of Guy's Hospital, in 1853. Sir James Goodhart had referred briefly to such from the anatomical side. Mr. Shattock had seen one or two, but they were rare. They were benign epithelial tumours arising in connexion with the hair follicles, and though benign closely resembled squamous-celled carcinomata in structure. He suggested the name "folliculoma." Calcification of the keratinising epithelium occurred in varying degrees, but it might be absent. They were not of the kind described by Malherbe (1881) as "calcifying epitheliomata of the sebaceous glands," which were keratinising and calcifying papilliferous cysts of the hair follicles. In birds there were peculiar "tumours" due to the retention of feathers in groups of follicles, accompanied with the accumulation of desquamate [illegible] cysts, as distinguished from [illegible] however, more comparable to [illegible] subject than to the proper [illegible] The peculiarity of the tumour exhibited was its remarkable opacity and whiteness. This was not due to calcification, nor was it due to the kind of saponification which rendered the fat opaque in "fat necrosis." The last possibility was excluded by microchemical tests. The opacity remained after the action of ether and alcohol, and the addition of hydrochloric acid produced no change; there was no liberation of droplets of oleic acid from any calcium oleate present, such as occurred in fat necrosis. The singular physical characters were due to the presence of a skein in the epithelial cells, of vast collections of which cells the growth consisted. This skein occurred in cells answering to the stratum corneum; in some cells it was very loose and open, in others closer and finer. It apparently was the same in kind as the delicate feltwork in the cells of the stratum corneum of the thick epidermis from the heel. Using the term "eleidin" rather as a generic one than as meaning absolutely the granules and flakes in the stratum granulosum, Mr. Shattock ventured to name the tumour an "eleidoma," after Virchow's manner of using such a term as psammoma; for though the last was an endothelioma it was one in which a particularly large amount of calcification of the endothelial whorls was encountered; and the master had thought this of sufficient importance to deserve a distinctive name.

SECTION OF LARYNGOLOGY.

Exhibition of Specimens and Cases.

A MEETING of this section was held on March 6th, Dr. D. R. PATERSON, the President, being in the chair.

Dr. H. J. DAVIS showed the following:—

1. Pathological specimens of Tonsils from a case of Lymphatic Leukæmia in a boy aged 7 years.

2. Preparation from a child, aged 2, showing the left recurrent laryngeal nerve involved in a mass of lymphomatous glands.—Sir FELIX SEMON remarked upon the rarity of laryngeal paralysis in children as resulting from lymphomatous glands.—Dr. A. BRONNER, Mr. E. B. WAGGETT, Sir STCLAIR THOMSON, and the PRESIDENT also discussed the exhibit.

3. Photograph showing two primary sores on the lip and angle of the mouth of a patient aged 22.

4. A man, aged 70, with Necrosis of the Hard Palate since the age of 10 years.—The PRESIDENT suggested that the necrosis was due to congenital syphilis.

5. A man, aged 50, showing a large Pulsating Vessel on the Posterior Wall of the Pharynx.—Mr. W. D. HARMER thought that the vessel was an abnormally placed internal carotid artery, and related a case in which a complete coil of that artery was removed during the operation for adenoids.

6. A woman, aged 45, with Loss of Septum and Columella of Nose.—Dr. WILLIAM HILL, Dr. DAN MCKENZIE, Dr. F. DE HAVILLAND HALL, and Sir STCLAIR THOMSON discussed the case, and the PRESIDENT remarked on the support to the tip of the nose which is afforded by the lateral nasal cartilages.

7. A woman, aged 44, with Malignant Disease of the Ethmoid extending along the antral roof and perforating the maxilla at the outer angle of the orbit; two operations.

8. A woman, aged 30, with Redness, Infiltration, and Œdema of the Nose and both Cheeks of six months' duration; there was an empyema of the left antrum.—The PRESIDENT remarked upon the rarity of the typical signs of antral suppuration as described by the surgical text-books.—Dr. E. A. PETERS suggested that the condition was entirely due to a septic fissure which was present in the right nasal vestibule.

Mr. W. STUART-LOW exhibited a case of a man, aged 50, showing Columnar-celled Epithelioma of the Nasal Cavity and Left Antrum.

Mr. HERBERT TILLEY showed a Laryngeal Tumour; ? adenoma of right ventricular band. He stated that the pathologist's report showed that the condition was one of adenoma of laryngeal ventricle.—Mr. F. A. ROSE disagreed with the report upon the microscopical section shown with the case, and suggested that the condition was chronic inflammation.—Sir FELIX SEMON thought the case was tuberculous laryngitis.—Mr. E. D. D. DAVIS related a similar case, and stated that Mr. S. G. Shattock would not give a definite opinion upon the microscopical section; later the case showed signs of tubercle of lung.

Mr TILLEY also showed Frontal Sinus Burrs for enlarging the fronto-nasal canal when operating by the intranasal method.

Dr. DAN MCKENZIE exhibited a Maxillary Antroscope modelled on the cystoscope. He deplored the lack of detail obtained by this form of instrument, as did also Mr. ROSE, Mr. WAGGETT, Dr. W. H. KELSON, and Dr. PETERS.—The PRESIDENT stated that he gave up attempting to make use of this instrument eight or nine years ago.

Mr. C. W. M. HOPE showed two cases of Acute Suppurative Frontal Sinusitis due to bathing.

Dr. PETERS exhibited a case of Lupus of the Nose; lupus or chronic tuberculosis of the larynx commencing in the left ventricle; improvement with B. emulsion; pregnancy followed by relapse of local condition and consolidation of right lung.—Sir STCLAIR THOMSON related that it was not unusual for women with nasal lupus to develop phthisis after marriage and motherhood.

Dr. JAMES DONELAN showed a female, aged 26, with a Growth on the Left Vocal Cord.—Mr. TILLEY thought it a case of intrinsic carcinoma, and Dr. DONELAN suggested late recurring papilloma.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Radium and Radiation as a Therapeutic Agent.

A MEETING of this society took place in the board room of the Great Northern Central Hospital on March 12th, Dr. T. WILSON PARRY, the President, occupying the chair.

Dr. W. S. LAZARUS-BARLOW gave a lecture on Radium and Radiation as a Therapeutic Agent. He said that finality was far from being reached upon many points in connexion with radiotherapy and indicated dosage as an example. Putting on one side the question of the injurious action of radium in sufficient quantity upon animal cells as being established beyond doubt, he addressed himself to certain propositions arising from that fundamental fact. Thus he pointed out that all varieties of cells were not equally injured by the same dose and suggested that in this fact might lie the explanation of the different degrees to which various growths responded to radium treatment. The crux of the whole radium question was whether radium acted upon a new growth in a different way from a thermocautery or a strong acid. There was some evidence that cancerous cells when irradiated short of death could induce an active immunity and he instanced the observations of Mr. Clifford Morson, Dr. B. H. Wedd, and Dr. Charles Russ in this connexion. If such an immunity reaction were produced it would probably be strictly specific for the individual, so that the production of an "anticancerous" serum analogous to antidiphtheric serum seemed highly improbable. He insisted upon the necessity of histological examination, and especially upon the importance of examination for Altmann's granules in the case of sarcoma, whenever radium was about to be used for a new growth. He further insisted upon the necessity of periodic examination of radium tubes by the physicist in order to be certain that radium was actually present in the quantity that the surgeon believed. He thought that besides its use in frankly inoperable cases radium should be tried in cases in which surgical operation, though not impossible, was notoriously unsatisfactory—*e.g.*, malignant neoplasms of the tonsil. On the other hand, where surgery could show a fair percentage of success the use of radium in place of the knife was not indicated at the present time, whatever might be the case in the future. Certainly, upon experimental grounds, use of radium immediately after surgical removal of a growth appeared to be contra-indicated; this was not the case with X rays, and no explanation of the apparently different behaviour of the X rays and the closely allied gamma rays of radium could be given at present. Finally, he pointed out that when a growth had been absorbed after radium treatment the products of the disintegration of that growth must have been taken up into the system at large, and he suggested that so long as the individual had not eliminated these disintegration products it was indicated by pathology that he would be in an unsatisfactory condition for any surgical treatment.

The PRESIDENT thanked Dr. Lazarus-Barlow in the name of the society for a lucid and interesting lecture, and said that everyone present had paid great attention to the line of thought indicated.

Dr. H. C. G. SEMON, in the discussion which followed, desired to associate himself with the President in an expression of his very cordial appreciation of Dr. Lazarus-Barlow's exceedingly lucid and interesting lecture, and referred shortly to a case which amply illustrated the latter's warning against the use of radium immediately subsequent to surgical removal of malignant growths. A well-known surgeon recently removed an epithelioma from the pyriform fossa by lateral pharyngotomy in an old man of 74. Much against his inclination he was persuaded to insert a tube containing 100 mgm. of radium in the wound, which was partially left open for that purpose for a period of 24 hours. Ten days later, after primary union had taken place, the whole wound broke down and a slough of the size of half-a-crown formed in the pharynx and led to a fistulous communication with the exterior, a result which was entirely outside the very considerable experience of the operator, and one which in his opinion could only have been produced by the devitalising action of the radium emanations on the normal tissues. Regarding the quantity of radium best employed as a dose at the present time Dr. Semon quoted from the experiences of Professor Bumm and Professor Döderlein,[1] who had had considerable experience in the treatment of malignant disease of the cervix and uterus. These authors had entirely given up the use of large doses and their practice was to use not more than 50 to 60 mgm. of the salt at any one application. Professor Bumm had stated that 300 mgm. doses would produce a rise of temperature as high as 106° F. in a few hours, and that 500 mgm. were positively dangerous to life. Dr. Semon asked if Dr. Lazarus-Barlow could support this statement from his own experiments, and also whether his opinion of lead filters coincided with that of Professor Bumm, who had stated that they should never be used because of the dangerous secondary radiations produced in them by the γ rays. This author maintained that they were the probable cause of the hyaline degeneration of normal fibrous tissue, which not infrequently followed the application of radium after a latent period of six months to a year, and which had in consequence of the production of hard strictures led to the erroneous belief that a malignant recurrence was in course of development. Dr. Semon asked if the lecturer had ever met with this complication.

Dr. W. A. MALCOLM asked Dr. Lazarus-Barlow how it was that X radiation was of such undoubted value in recurrent nodules after breast operations, whereas the contrary was true of radium.

Mr. CECIL ROWNTREE quoted a case of periosteal sarcoma of the femur in a woman, where the growth had not been much affected by radium, but where the effect on the patient was wonderful, for instead of being bedridden she could walk up and down the ward and was quite cheerful.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Diseases of the Œsophagus.

A MEETING of this society was held at the Royal Devon and Exeter Hospital on Feb. 20th, Dr. RANSOM PICKARD, the President, being in the chair.

Dr. WILLIAM HILL (London) gave a lecture on Modern Methods of Diagnosis and Treatment in Diseases of the Œsophagus, with especial reference to the Employment of Radium in Malignant Stricture. After demonstrating the method of inspection by œsophagoscopy and œsophago-gastroscopy on patients under cocaine anæsthesia, 100 lantern slides were shown illustrating the following points: 1. The mode of formation, anatomical characteristics, radiographic and œsophagoscopic diagnosis and treatment of so-called "œsophageal pouches" (pharyngeal diverticula), with skiagrams of six cases under the author. 2. The diagnosis and treatment of foreign bodies. 3. Non-malignant strictures, with special reference to treatment by various methods of dilation and by intubation. No unequivocal case of idiopathic spasm—e.g., cardiospasm—had been met with in the author's large experience. 4. Various types of malignant stricture. 5. The forms of radium apparatus employed by the author, their method of introduction, statistics of results, and skiagrams taken before and after treatment. The improvement in many instances was not only marked as regards subjective symptoms, but was objectively shown by the œsophagoscope and by radiography. All present had an opportunity of observing through the œsophagoscope a stricture, formerly fungating, which had been held in check for four years by eight applications of radium made at intervals.

At the termination of the lecture a vote of thanks, proposed by Dr. W. GORDON, and seconded by Mr. R. A. WORTHINGTON, was awarded to Dr. Hill by acclamation.

Treatment of Uterine Myomata by X Rays.

A MEETING of this society was held at the Royal Devon and Exeter Hospital on March 13th, Dr. PICKARD, the President, being in the chair.

Dr. J. DELPRATT HARRIS read a paper on the Treatment of Uterine Myomata by X Rays. In this it was stated that hitherto after the continued use of styptics and prolonged rest there remained to the family attendant no other course but that of hysterectomy as the last resource. No one could approach this operation with feelings of satisfaction until all other means had been given a fair trial. Within the last few years, however, a third course of procedure had been coming to the front, that of treatment by the therapeutic use of X rays. Although many technical considerations intervened relative to bulk, depth, and dosage, they would appear to have crystallised into two main schemes of treatment, the French scheme brought into existence and elaborated by Dr. Bordier of Lyons, more particularly; and the German scheme elaborated by Albers Schönberg of Hamburg, and Gauss of Freiburg, and others. Looking at this form of treatment by X rays from the point of view of the family practitioner, it should be noted that the patient might be up and about, as far as hæmorrhage would allow, if that was a prominent symptom. The patient should have a sitting every day or every other day for nine sittings. These nine sittings constituted a cycle. It was wise to allow 21 days to elapse, when a second cycle should be given. This might be repeated five or even six times, but it was rarely necessary to exceed this number of cycles, for the treatment seemed to be cumulative, and shrinking seemed to go on after the treatment was left off. The sittings were conducted so that the uterus and tumour received a dose of X rays of about one to two milliampères; at the second sitting the right ovary was treated; at the third the left; at the fourth the uterus and tumour again; and so on. In particular cases the patient might be turned on her face and hands, and the posterior aspect of the tumour similarly treated through the sacrum and sciatic notches. Under this system an artificial menopause was brought about, and the patients suffered from flushings, whilst the tumour notably shrank in size, but not always to disappearance, whilst hæmorrhage was abolished, and the patients expressed themselves as feeling better. The German system did not differ in principle from the French, but their tendency seemed to be to give the heaviest possible dose from multiple cross-fire directions for a few days or even hours with a long interval of rest when the course was repeated. In each form of treatment careful filtering of each dose is carried out with 2 mm. to 3 mm. of aluminium. The notes of four cases were read, in each of which notable improvement had occurred, and artificial menopauses established with the usual climacteric symptoms of flushings, with shrinking of the tumour. Thus one case, 39 years of age, commenced treatment in August, 1912. In May, 1913, she was able to undertake all her household duties, looking and feeling quite well. Another case commenced treatment in October, 1912, and in December slight hæmorrhage occurred, but none after. She was able to attend to her household duties after the fifth cycle. In a third case a woman of 43 was similarly treated. It was commenced in September, 1912, and in April, 1913, it was noted that the menopause was complete for four months. It had commenced in the third cycle. In July, at the end of the fourth cycle, she had a period lasting 36 hours only. In the fourth case a woman of 49 had a fairly large fibroma occupying the position of a seven months' infant. Although, as in all the other cases, hæmorrhage was a marked feature, it ceased during the first cycle and did not return. In each of these cases the appearance of exsanguination gradually changing to that of health was most satisfactory.

Dr. F. A. ROPER reported the case of a widow, aged 42, suffering from a somewhat rapidly growing fibromyoma uteri. The chief symptom complained of was pain at the monthly periods, so severe that she was prostrated for four days at every period, and no doubt partly resulting from this she was in an exceedingly neurotic state. The fibroid was estimated to be larger than a croquet ball. Treatment was commenced on May 9th, 1913, on the lines of the Hamburg school, series of five irradiations through five portals of entry—two behind and three on the abdomen—being given on successive days, a clear fortnight elapsing between each series. Seven series were given, a filter of 2 mm. aluminium being used. A sitting comprised five to ten minutes with current 3 to 6 ma. After one normal and two scanty periods six months' amenorrhœa resulted, with complete relief of pain, and shrinkage and sclerosis of the tumour to the size of a tangerine orange. Menopausal symptoms appeared which were relieved on the reappearance of the menstrual flow, which was unaccompanied by pain. There was no trace of dermatitis save slight browning. Comparing this method with that of Professor Gauss, Dr. Roper preferred it on account of the fact that the results were in every way as good as those of Gauss. The excessive doses given by the Freiburg school were, therefore, unnecessary.

---

[1] Brit. Med. Jour., Dec. 13th and 27th, 1913.

In the discussion which followed the reading of these two papers Mr. F. W. LANGRIDGE remarked on the resemblance between the uterus and the prostate gland, and asked the readers of the papers whether they had extended the treatment to cases of prostatic enlargement.

Dr. GORDON considered that Dr. Harris was a pioneer in England as regards this treatment, and related a case where mitral stenosis in conjunction with fibromyomata made the operation undertaken for the latter to be fraught with the gravest anxiety. He asked the reason why Bordier considered those cases which have ceased to menstruate unsuitable for treatment.

Mr. C. E. W. BELL alluded to the method of Apostoli where glowing accounts were at first published, although nothing was now heard of this treatment.

Mr. A. L. CANDLER advised that women aged 40 and upwards suffering from fibromyomata, who were blanched from hæmorrhage, should be treated by X rays, and later on have the fibroids removed to guard against possible malignancy in the future. He regarded the X ray treatment as a preliminary to operation.

Dr. R. V. SOLLY stated that tumours of the prostate were frequently composed largely of adenomatous tissue which would be affected by X rays to a very slight extent.

Mr. A. C. ROPER, speaking from the surgeon's point of view, expressed the relief he would feel when freed from the overwhelming responsibility of doing serious operations on cases weakened and depoverished by hæmorrhage. The advantages of X ray treatment were: (1) saves risk of operation; (2) saves necessary rest of six months after operation; (3) the course of six months' treatment less costly, no nursing required, no absolute rest in bed, no risk, and steady improvement. He considered the German method to be most convenient where sittings follow daily.

Dr. HARRIS, in his reply, stated that X rays had a beneficial effect on the enlarged prostate, and that zinc ionic treatment through the rectum had also proved useful. Apostoli's method was merely a form of ionisation of fibroids.

Dr. R. EAGER reported a case of Aneurysm of the Left Ventricle bursting into the pericardium. There was much atheroma of the aorta. He also showed the heart and aorta of a case where rupture of the aorta had taken place into the pericardial sac. There was a specific history in this case.

EDINBURGH OBSTETRICAL SOCIETY.

Etiology of Eclampsia.—The Registration of Stillbirths.

A MEETING of this society was held on March 11th, Sir J. HALLIDAY CROOM, the President, being in the chair.

Dr. JAMES YOUNG, in a paper and epidiascopic demonstration, discussed the Etiology of Eclampsia. He referred to the well-recognised fact that albuminuria and eclampsia were especially apt to be associated with red infarcts in the placenta. As, however, eclampsia was found with an apparently healthy placenta, and no toxæmia where there was definite infarction, the association remained somewhat of a mystery. It was usually believed that the infarction was merely to be looked upon as an accompaniment or as a result. Dr. Young showed from many points of view that infarction was due to involvement of the maternal vessels and not to disease of the fœtal vessels. It had long been known that the chorionic elements could live where there was no fœtal circulation—e.g., in the early trophoblast, in hydatid mole, and in chorion epithelioma. In accidental hæmorrhage, which was known to be especially associated with albuminuria and eclampsia, he showed evidence of placental disease in apparently healthy placentæ. This disease would only be possible where a certain time had elapsed between the hæmorrhage and the removal of the placenta. In this way it was possible to explain the fact that in only 50 per cent. of the cases was there a toxæmia. Dr. Young referred to experimental proof of his thesis that the placenta was the source of the poison. He had isolated a substance from healthy placentæ, which had been appropriately treated, that induced severe convulsions in animals and, in addition, focal necrosis in the liver, a change that was recognised to be especially characteristic of eclampsia.—The PRESIDENT stated that he had learned a great deal. The villus if cut off entirely from the fœtal supply could live in healthy maternal blood. Dr. Young had shown that infarcts were surrounded by blood clots and had also shown that these blood clots pressed upon the surrounding parts of the placental tissue, and by so doing destroyed its vitality. This degenerated part of the placenta was the source of the toxin which caused eclampsia. That point of view had not been presented before. If it be that this toxin was the cause, then Dr. Young had proved his case, because he had shown that he could produce very similar changes in animals. If this were so, a very great advance had been made in the demonstration of the cause of eclampsia. It was, however, a mystery still. With regard to accidental hæmorrhage, he was not so sure that only 50 per cent. were associated with albuminuria.—Dr. D. BERRY HART asked where the toxins came from in the infarct. The toxins were in the blood and also the tissue. The toxin was deposited in the clotted blood before the infarct took place. He did not think that Dr. Young could say that these infarcts were the cause of the eclampsia; if that were so they should at once deliver the women and remove the placenta.—Dr. W. FORDYCE said that in eclampsia certain changes occurred in the liver and kidneys, and he thought Dr. Young had brought no proof to show that the poison was from the placenta any more than from the liver and kidneys.—Dr. R. W. JOHNSTONE asked how Dr. Young applied his theory to the cases where eclampsia occurred after delivery.—Dr. H. OLIPHANT NICHOLSON, Dr. J. W. BALLANTYNE, and Dr. A. C. GUTHRIE discussed the paper.—Dr. YOUNG, in his reply, stated that in the experiments he employed healthy placentæ specially treated to reproduce the diseased condition.

Dr. BALLANTYNE read a paper on the Registration of Stillbirths. He said that the first difficulty was one of definition. Notification was giving notice or making intimation; registration implied declaration and inscription. The Notification of Births Act of 1907 required notice within 36 hours; registration within 42 days. The Notification of Births Act had been adopted only in 316 out of the 1822 Local Government areas in England and Wales; but these areas represented 18,000,000 persons out of a total population of 36,000,000. The persons upon whom the duty of declaring the birth was laid differed in the two cases. The Notification of Births Act went further than the Registration of Births Act of 1874, by calling for declaration of birth with respect to children born alive and to those born dead after 28 weeks' gestation. This involved, therefore, registration of a certain number of stillbirths. By far the most valuable contribution which had been made to the proper understanding of stillbirths and their registration of recent years was that contained in the Report of the Special Committee of the Royal Statistical Society on Infantile Mortality of December, 1912. The committee received replies from 103 registration officers all over the world. The registration of stillbirths was not compulsory in Great Britain and in certain of her dependencies, in Denmark, and in a few of the individual States of the United States of America. Numerous countries had compulsory registration of stillbirths; Great Britain and Ireland had been singularly dilatory in taking steps to acquire powers to discover the stillbirth rate in the population. The Statistical Society's committee stated that, as far as [illegible] are had up to the present [illegible] It was desirable that an [illegible] irth should be adopted. Some countries demanded that all births, alive or stillborn, [illegible] an even a fœtus after four [illegible] a very great difference in the [illegible] countries of what were con- [illegible] rt of the confusion depended on the lack of a correct view regarding ante-natal life. There were an ante-natal life and a post-natal life; and there was one great differentiating character—the respiration. In ante-natal life tissue respiration was dependent on the placenta; in post-natal life it was a pulmonary one and dependent on the atmosphere. If viability be chosen as the delimiting age, then he (Dr. Ballantyne) would prefer 24 weeks instead of 28 weeks, as every improvement in the construction of the *couveuse* and every advance in the feeding of the premature infant might alter the age of viability and make it earlier. But he was ready to concede 28 weeks for the sake of uniformity. "Completely born" required definition; it was when a child's head, trunk, and limbs were all outside the vulva; it was not necessary that the cord should be divided or the placenta expelled. "Dead-born child" should be applied to a child which after complete expulsion from the body of its mother showed that it had ceased to exhibit the signs of ante-natal life at some period prior to labour. Of course, the great sign of ante-natal death was to be looked upon as maceration. Ulceration was in no degree putrefaction. There were also those children who had died in the birth, whose hearts could be heard at the beginning of labour but who showed no signs of ante-natal life at the moment of birth; these might be called "dead-in-birth children" and the condition "intra-natal death." There were two groups of stillbirth—one which passed into post-natal death, and the other which was resuscitated by the efforts of the medical attendant. But resuscitation was not an accurate term—its meaning was restoration to life; but in these infants it was not so much a restoration as a substitution of one form of vitality for another. Dr. Ballantyne suggested the word "trans-animate," though it was not quite satisfactory. "Stillbirth" should be limited to those which have not assumed the characteristic phenomena of post-natal life. There was great necessity for the compulsory registration of these ante-natal and intra-natal deaths. Great Britain and Ireland stood almost alone among the civilised nations of the world in neglecting this attempt to discover how many lives in their population were lost before and at birth. The cause of these deaths, if known, could be added on [illegible] There had been a great reduction [illegible] the first year of life since special [illegible] to it. A Stillbirths Registration Act would give statistics and rouse effort to the greater care of the ante-natal child and to the prevention of congenital diseases. It had been calculated that no less than 35 per cent. of the total mortality under one year of life was due to congenital disease.—Dr. Ballantyne's paper was referred to the council for consideration and report to the May meeting of the society.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on March 12th, Colonel Bruce M. Skinner, M.V.O., A.M.S., the President, being in the chair.—Major E. T. F. Birrell, R.A.M.C., read an interesting paper entitled "Some Experiences of the Balkan Wars." Major Birrell went out to the Balkan wars under the British Red Cross Association, and was appointed by them commandant for the Red Cross services in Bulgaria. Two units were despatched to Bul[illegible] [illegible] surgeons, four dressers (me[illegible] ing orderlies, general dut[illegible] ment of each section was practically the medical and ordnance equipment of a section of a field ambulance without tents or vehicles, but with the addition of the then field pattern of X ray apparatus, a small petrol engine, and some special surgical equipment. The units on arrival at Sofia received orders to proceed to the front and open a hospital there. The journey as far as Jamboli was accomplished by rail. During the journey three types of ambulance trains were met with: (1) In Servia a specially fitted up train, consisting of covered baggage wagons for the patients, painted white with red crosses, and each fitted inside with eight wooden berths in two tiers, besides ordinary passenger coaches for the surgeons and attendants; (2) in Bulgaria ordinary passenger coaches, the wounded sitting or lying on the seats; and (3) ordinary baggage wagons, with straw or matting for the patients to lie upon. Major Birrell described the journey by road to Kirk Kilisse from Jamboli, and the difficulty of getting the men together in the morning when distributed overnight in billets. When the units arrived at Kirk Kilisse the wounded were just beginning to come in from Chatalja, where heavy fighting was going on; the slighter cases came first, but many looked worn and hungry, and many of the more severely wounded arrived with their bandages soaked with pus and blood. The hospitals were crowded even to the passages and landings. The Red Cross units were given a building in which to set up their hospital. Convoys of wounded were organised from time to time, the vehicles used being bullock and buffalo carts, both of which were innocent of any springs. The wounded were simply placed on fodder on the floor of the wagon. Very severe cases were, however, generally placed [illegible] ch mini- [illegible] medical [illegible], but at many stations the Bulgarian Red Cross Association had established rest camps, or at least places where bread could be obtained. The great problem at Kirk Kilisse was the supply of water. There was none laid on to the hospital; the supply had to be carried in barrels on bullock wagons. For drinking purposes the water was purified by the addition of bisulphate of soda; no ill-effects could be traced to the drinking water. Flies were a great pest; they swarmed in the tents and hospital; no attempt could be made to destroy the breeding-places of the flies, as these were too widespread. Cholera and enteric fever were the diseases of most interest, though no cases of the former came to the hospitals at Kirk Kilisse, but at Chatalja there were some 23,000 cases with 3000 deaths—a very low death-rate. Enteric fever was fairly common during the first war, but in the second only one case was seen. Most of the cases during the first war were treated in the Russian hospital by Dr. O. Clarke, with vaccine provided by the Royal Army Medical College. The results were very satisfactory, and Dr. Clarke is going to publish them. The Bulgarian war ration was satisfactory as regards its energy value. A most interesting point, however, was the sugar hunger, from which both staff and patients suffered. Regarding the effects of the sharp-pointed Turkish bullet, there did not appear to be any difference in the character of the wounds when compared with those from th[illegible] Servian bullet. All the wounded were septic. [illegible] from Chatalja, those in which [illegible] emorrhage had been plugged, and this was a very fruitful cause of sepsis. In both wars the [illegible] of iodine as an antiseptic was abundantly proved. A w[illegible] was found to be very sat[illegible] been condemned by foreign observers in the Balkan wars; this was no doubt due to the abuse of the drug which was noticed. The favourite Bulgarian application to a wound was [illegible] alcoholic solution of iodine on a swab on the end of [illegible] raw surface [illegible] the X rays was enormous; not only was time saved in diagnosis, but the treatment was rendered easy and accurate.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Leeds General Infirmary on March 1[illegible] the President, being in the [illegible] by [illegible] n [illegible] methods of suggestion and psychotherapy so that they might be employed with precision instead of indeliberately [illegible] as at present. While pointing out that [illegible] psychotherapy and occasionally [illegible] s experience it was but seldom [illegible] in many cases. More [illegible] of Dubois [illegible] patient by graduated conversations. He pointed out the great benefit that resulted from the employment of deliberate suggestion in regard to hospital cases. He also emphasised the fact that the "rest-cure" had been largely used in unsuitable cases with consequent aggravation of the symptoms; more often a "work-cure" was required for the restoration to normal of the patient's perverted over-attention to his own ailments.—Dr. R. G. MacD. Ladell showed an unmarried woman, aged 41, who had a history of occasional vomiting over two years, gradually increasing in frequency. The patient became very emaciated. Drug treatment, &c., had no effect. Laparotomy was performed in July, 1912; no morbid condition was found, and nothing was done beyond dividing some peritoneal adhesions. Slight improvement was followed by a relapse to the former state. She was treated by hypnotic suggestion in January, 1913. Deep sleep and amnesia were obtained from the first with definite improvement. There was complete cure after about a dozen sittings, and no relapse had occurred to date. —Mr. W. Thompson showed:—1. Two Calculi which were impacted in the ureter near the base of the bladder, and which had been removed by the extraperitoneal operation. 2. A calculus impacted in the ureter. The case had been regarded as one of appendicitis and appendicectomy had been performed, but the symptoms persisted. The diagnosis was cleared up by X ray examination.—Dr. C. Oldfield showed a specimen of Ectopic Pregnancy which continued to the sixth month of gestation. The patient, aged 30, was dilated and curetted a year ago for sterility. Six months ago she missed her period for the first time; three weeks later she began with symptoms (chiefly vaginal blood discharge and pelvic pain) which continued with intervals up to December, 1913. Abdominal symptoms with more bleeding from this date to the present were the leading features. The physical signs resembled those of a retroverted gravid uterus for which it had been mistaken. At the operation a partly macerated sixth month fœtus lay free amongst the small intestine. The placenta was large and infiltrated with blood clot, was attached to the pelvic organs, and firmly adherent to the right tube. This, the site of original implantation, was removed with the placenta attached. Separation of the placenta resulted in free hæmorrhage, which soon stopped. The abdomen was closed without drainage, and the patient is making satisfactory recovery.—Mr. S. W. Daw gave a demonstration of a method of reducing intussusception by forceps dilatation at the point of constriction.—Dr. A. H. Miller demonstrated a method of growing tubercle bacilli on media prepared from sperm oil and other waxy substances.—Mr. J. F. Dobson showed specimens from some cases of Nephrectomy. In one case a closed tuberculous pyonephrosis on the right side, probably of many years' duration, was associated with tuberculous disease of both testicles and of the prostate. After investigation of the secreting capacity of the left kidney by cystoscopic examination the diseased kidney was removed. The patient improved very quickly after the operation, and the painful enlargement of the testicles diminished rapidly.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 20th, Dr. David Ross, the President, being in the chair.—Mr. R. M. Vick showed: 1. A girl, aged 6, with a Tuberculous Abscess over the Lower End of the Radius, and its skiagram. 2. A boy, aged 4, with a Periosteal Tuberculous Abscess over the Iliac Crest, and its skiagram. 3. A man, aged 24, whose right testicle and epididymis were enlarged and tender, and whose right prostatic lobe was enlarged. There was a history of 18 days' duration and none of gonorrhœa. 4. A skiagram of a Transverse Fracture of the Patella in a man with no other symptom than stiffness on extreme flexion of the knee. 5. A baby with two fifth toes on each foot. The skiagram showed the related metatarsals were nearly double the normal width. 6. A young woman with a Perforation of the Soft Palate, whose Wassermann reaction was positive. 7. A man, aged 45, with Internal Strabismus, who suffered an intracapsular fracture of the femur as a boy; is now the subject of phlebitis of the internal saphena, and has both testes atrophied.—Dr. A. Feiling showed: 1. A man aged 46, with the typical signs of Pseudo-hypertrophic Paralysis that began 20 years ago. There was a family history of the disease. 2. A man, aged 40, with Graves's disease without exophthalmos, with hand tremors on extension, an enlarged thyroid, and pulse varying between 108–116, in whom there had been recurrent attacks of tonsillitis. 3. A woman, aged 47, who had marked Right Hand Tremor of large excursion and some of the left hand of less excursion which developed in a night and has continued for two and a half years. The right grasp is weaker than the left. The right leg drags a little in walking. Dr. Feiling thought a vascular lesion at the base of the mid-brain the probable pathology. 4. A woman, aged 67, of wooden facies, with Tremor of both Hands when at rest and some rigidity of the arms due to paralysis agitans.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 11th, Dr. P. Watson-Williams being in the chair.—Dr. D. A. Alexander showed a case of Varicosity of the Collateral Venous Circulation as a result of thrombosis of the common iliac vein during enteric fever.—Dr. F. H. Edgeworth read notes on a case of Enlarged Thyroid with Tachycardia. He did not regard the case as one of Graves's disease owing to the absence of wasting and the regularity of the heart's action, and also the fact that the administration of thyroid extract cured the condition. He suggested that the tachycardia was possibly due to pressure of the thyroid on the vagi.—Mr. C. F. Walters described four cases in which he had tried the autoplastic intramedullary bone pegging of fractures. A portion of the patient's tibial crest was used to manufacture the peg. The method was not successful, union being slow and faulty, and in two of the cases fracture of the tibia resulted from weakening at the site of removal of the peg.—Mr. E. W. Hey Groves showed a loan collection illustrating the operative treatment of fractures, and emphasised the advantage of bolts which go right through the bone over screws which soon become loose.—Mr. Greer stated that he considered that the use of bolts involved too extensive a trauma and too long an operation. He had found Lambotte's apparatus of great use.—Mr. W. Sheen said that he was doubtful of the final result in operated cases, and considered that bad anatomical was frequently found in conjunction with good functional result.

MIDLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in Birmingham on March 3rd, Mr. Christopher Martin, Vice-President, being in the chair.—Dr. O. E. Purslow showed a specimen of Pyometra due to Intracervical Cancer. The specimen was removed from a multipara, 59 years of age, who complained of irregular hæmorrhage of 15 months' duration following several years' amenorrhœa. There had also been difficulty in micturition. On examination, a symmetrical tumour was found reaching above the pubes and filling the pouch of Douglas. This was diagnosed as an enlarged and retroflexed uterus. The cervix was situated high up behind the pubes, and only the posterior lip could be reached by the finger. This was normal. A degenerated fibroid was suspected, and it was not until the abdomen was opened that the exact nature of the disease was recognised. Panhysterectomy was performed, and the patient made a good recovery. The unusual features of the case were the large size of the pyometra, the uterus containing two pints of foul-smelling pus, and the fact that the cervical carcinoma could not be felt on digital examination per vaginam.—The case was discussed by Mr. F. Edge, Professor Thomas Wilson, Mr. L. Kirkby Thomas, Mr. H. Beckwith Whitehouse, and Mr. Martin.—Mr. J. Furneaux Jordan showed a specimen of Double Ovarian Cystic Tumour of intraligamentary development.—A discussion followed, in which Professor Wilson, Mr. Edge, Dr. Purslow, Mr. Martin, and Mr. Jordan took part.—Professor Wilson showed a specimen of Diffuse Ovarian Suppuration with Tubo-peritoneal Cyst.—Mr. Martin, Mr. Jordan, Dr. Purslow, and Mr. K. M. Pardhy entered into the discussion of this case.—Mr. Edge showed a specimen of Carcinoma of the Ovary with metastasis at base of the appendix vermiformis.—The case was subsequently discussed by Mr. Whitehouse and Mr. Edge, and the specimen was referred to a pathological subcommittee consisting of Mr. Whitehouse, Mr. Edge, and Mr. Smallwood Savage.—Professor Wilson read a short communication upon Concealed Accidental Hæmorrhage: Cæsarean Section: Recovery. The specimen, consisting of a uterus removed by Cæsarean hysterectomy, was of particular interest, inasmuch as it showed extensive subperitoneal and intramuscular hæmorrhages. These were most evident at the uterine cornua. Microscopical preparations showed extreme degeneration of the myomatous elements in the uterine wall. The degeneration appeared to be hyaline, but its exact nature was so far undetermined. The case was of considerable interest because it raised several new points in the pathology and causation of the hæmorrhage in this condition.—In the discussion which followed Mr. Martin, Mr. Jordan, Mr. Savage, Mr. Edge, and Dr. W. H. C. Newnham took part.—Mr. Edge read a short communication upon a case of Inversion of the Uterus. The patient, aged 28, a 3-para, was admitted to the Women's Hospital, Birmingham, on August 17th, 1913. Five days previously she had given birth to her fourth child and had been attended by a midwife. No exact details were obtainable as to what had previously transpired, but she was sent into hospital as a case of puerperal fever following post-partum hæmorrhage. On admission the woman was acutely ill, with a pulse of 160 and temperature 104° F. Preparations were made for obtaining a swab from the uterine cavity, but upon vaginal examination a rounded mass was felt within the vagina. Bimanually the uterus was absent, and a diagnosis was made of "uterine inversion." It seemed hopeless to perform any abdominal or vaginal section. Nevertheless, by dilatation of the cervix from above and reduction of the parts last inverted the condition was gradually reduced. The uterine cavity was cleansed with hydrogen peroxide and packed with iodoform gauze. The following day the patient's temperature was 105° and the pulse 160. She was treated with polyvalent antistreptococcic serum and eventually made a perfect recovery.—Mr. Martin, Mr. Jordan, Dr. Purslow, and Professor Wilson took part in the discussion upon this case.

Reviews and Notices of Books.

Acute Abdominal Diseases, including Abdominal Injuries and the Complications of External Hernia.

By JOSEPH E. ADAMS, M.B., M.S. Lond., F.R.C.S. Eng., Senior Assistant Surgeon, East London Hospital for Children, &c.; and MAURICE A. CASSIDY, M.A., M.D., B.C. Cantab., F.R.C.P. Lond., Physician with Charge of Out-patients, St. Thomas's Hospital, &c. London: Baillière, Tindall, and Cox. 1913. Pp. 541. Price 12*s.* 6*d.* net.

THERE is hardly any more difficult department of medicine than the acute affections of the abdomen, especially as regards diagnosis, and as the affections include some which may be called medical and also many which are undoubtedly surgical, the subject can be adequately treated only by the combined efforts of a physician and a surgeon. Therefore we consider that the authors have done well to collaborate in the production of this volume, and the result is in every way satisfactory. The chapter on the anatomy of the abdomen is adequate, and we are glad to see that special attention has been paid to the peritoneal fossæ, which are the cause of some of the most puzzling of the acute abdominal conditions. The chapter on the investigation of the abdomen is well written, and should afford useful assistance to the inexperienced. The value of the information given by a leucocyte count is emphasised, but the authors point out that Cabot has shown that in bleeding gastric ulcers without any perforation the leucocytic count may vary from 12,000 to 24,000 in 27 per cent. of the cases.

The chapter on laparotomy is admirable. We agree entirely with the advice given that it is very undesirable, if it can possibly be avoided, to move a patient with an acute abdominal condition for the purpose of operation. While it is generally necessary to take the poorer patients from their homes to the hospital, for an operation is usually impossible at their homes, in the case of private patients it is much better not to require the removal even to a nursing home, for an abscess may give way and a fatal general peritonitis may result.

In the chapter on intestinal obstruction we find an interesting table in which 500 cases of obstruction occurring at St. Thomas's Hospital are analysed; from this table it appears that in more than one-third of the cases the condition present was intussusception; carcinoma of the cæcum and colon formed 15 per cent.; and adhesions provided 12 per cent.; but no other cause gave rise to more than 10 per cent. of the cases.

After the subject of intestinal obstruction has been fully treated the various abdominal organs are taken in turn, and the conditions which may cause acute abdominal symptoms are discussed. Appendicitis naturally occupies a very large portion of the space, and the authors express the opinion, which is indeed held generally now, that immediate operation is always indicated. The chapter on the complications of external hernia is good, and we would especially draw attention to the chapter on abdominal injuries, by no means the least difficult of the conditions giving rise to acute abdominal symptoms. The final chapter is important, for it deals with diseases which simulate acute abdominal lesions. We agree with the authors that an examination of the chest, of the knee-jerks, and of the pupils should never be omitted in any case in which the question of a laparotomy has arisen.

We have been very pleased with this book; it is a clear exposition of a very difficult subject.

Beri-beri.

By Captain EDWARD B. VEDDER, A.M., M.D., of the Medical Corps of the United States Army. With numerous illustrations in the text and 5 coloured plates. London: John Bale, Sons, and Danielsson. 1913. Pp. 427. Price 18*s.* net.

THIS work, to which was awarded the Cartwright Prize of the Medical Department of the Columbia University, New York, for 1913, has been published by permission of the Surgeon-General of the U.S. Army. The book, so far as we are aware, is the first complete work of its kind to be issued in the English language dealing with beri-beri in the light of the many recent discoveries and marked advances in our knowledge of this hitherto baffling disease. The author is well known as an experimental investigator of the malady, concerning which he has published many interesting papers in the *Philippine Journal of Science*. He has also had exceptional opportunities for becoming practically acquainted with the disease while acting for some continued time as a member of the U.S. Army Board for the study of tropical diseases as they exist in the Philippine Islands, where, as in other parts of the Far East, beri-beri has played havoc among the natives, and especially among the coolies employed on plantations and estates. Captain Vedder defines the malady as an acute or chronic disease characterised by changes in the nervous system, and particularly by multiple peripheral neuritis, resulting from faulty metabolism, usually seen only in those persons who eat rice as a staple article of diet, and directly caused by the deficiency of certain vitamines in the food. The value of the researches made by Fraser and Stanton in the Federated Malay States is acknowledged, as also those of Casimir Funk of the Lister Institute and others, including such pioneers as Eijkmann and Braddon.

The book comprises 16 chapters in which are given a short history of beri-beri, its distribution, prevalence, pathology, and symptomatology; the question of rice and its preparation for human food; the etiology of the malady, and whether it is to be regarded as a specific disease caused by an intoxication, or an infection, or is due to some deficiency of an essential element in the dietary; polyneuritis gallinarum and the beri-beri of animals; infantile beri-beri, ship beri-beri, and epidemic dropsy. Certain theoretical and practical considerations are also discussed, including the prevention of the malady. The author in his conclusion suggests the appointment of an international commission of delegates representing the great nations interested in the prevention of beri-beri, to discuss the advisability and practicability of generally extending the use of undermilled or unpolished rice by means of a tax levied by all nations on highly milled or polished rice, or by any other better method devised by the commission. Included in the book is a very extensive bibliography of beri-beri, and although the author states that it is "not absolutely complete" it cannot be far off, for it contains nearly 1000 separate references from all parts of the world where beri-beri has been observed.

We warmly commend this volume to all who wish to study the etiology of this dangerous disease and the data on which the modern treatment and prophylaxis of the malady are based. The book appears at a very opportune time and should find many readers.

Manual of Operative Surgery.

By JOHN FAIRBAIRN BINNIE, M.B., C.M. Aberd., Surgeon to the General Hospital, Kansas City, Mo., &c. Sixth edition, revised and enlarged, with 1438 illustrations, a number of which are printed in colours. London: H. K. Lewis. 1913. Pp. 1251. Price 30*s.* net.

IT is by no means easy to find words of greater praise to bestow on this edition of this work than we employed for the earlier issues. The book is indeed improved, for it contains several new operations; but it was for all practical purposes perfect before. Whoever criticises this work must first understand its idea, which is to include much that is not to be found in the ordinary text-books of surgery and to exclude much which the text-books contain. It is intended to provide the practising surgeon with information he may need in the performance of an operation; it gives the various methods which have been and are still employed, but only in such detail as a surgeon would require; it omits much that is known to all surgeons. The work is unique, and it should prove in the future as it has proved in the past of the greatest assistance to all who wish to know the various methods of doing an operation. The book now includes several sections omitted in some of the earlier issues, and we commend it to all who operate.

Lehrbuch der Nervenkrankheiten für Aerzte und Studierende.

Von Professor Dr. H. OPPENHEIM, in Berlin. Sechste wesentlich vermehrte und verbesserte Auflage. Mit 523 Abbildungen im Text und auf 14 Tafeln. Two volumes. Berlin: S. Karger. 1913. Pp. 1926 Price, bound, 56 marks; paper, 52 marks.

FIVE years have elapsed since the appearance of the fifth edition of Professor Oppenheim's classic treatise on nervous diseases. These have been years of phenomenal progress in neurology. During them our knowledge has been materially advanced as regards the following subjects, to select but a few at random: epidemic poliomyelitis, syphilis, salvarsan, the glands of internal secretion, the sympathetic nervous system, the physiology and pathology of the vestibular nerve, and the cerebellum. To take account of all the advances in neurology alone is laborious enough, and to adapt them for the purposes of an up-to-date text-book is indeed a formidable task. Professor Oppenheim, however, is nothing if not thorough. The literature of neurology in all languages has been laid under contribution; innumerable separate articles and communications have been perused and their contents noted, with the result that on any topic in neurology the physician will herein find, not merely a survey of the particular subject, but valuable references to literature concerning it. And let it not be supposed that these two volumes of 1926 pages are but a long series of abstracts strung together; nothing strikes the reader familiar with the subject material more than the critical acumen of the author in separating essentials from non-essentials; nothing is more noteworthy than his skill in emphasising what is known and proved and his judicial weighing of evidence where the data are uncertain or incompletely investigated.

Professor Oppenheim's original contributions to neurology have been many and valuable, but it may be questioned whether any reveals more ability than this great compilation. Apart from the descriptions of diseases, there are chapters on anatomy and physiology, and on general symptomatology, each one of which is a book in itself. By original illustrations and others culled from outside sources, by indexes and abundant bibliographical references, by the judicious use of large and small texts, the work has been made as complete and as practical as is possible. Oppenheim's sixth edition is a monument of industry and intellectual power.

Grundriss der Dermatologie.

Von J. DARIER, Médecin de l'Hôpital Saint Louis; autorisierte Übersetzung aus dem Französischen von Dr. Phil. et Med. KARL G. ZWICK, aus Cincinnati, Ohio, U.S.A., mit Bemerkungen und Ergänzungen von Prof. Dr. J. JADASSOHN, Direktor der Dermatologischen Universitätsklinik in Bern. Mit 122 Textfiguren. Berlin: Julius Springer. 1913. Pp. 543. Price, paper, 22 marks; bound, 24.50 marks.

THE dermatology of Darier is widely known, and it has been appreciated by all who have read it, so that no surprise can be felt that it has been translated into German. The value of the translation is measurably enhanced by the facts that Professor Jadassohn has interspersed remarks here and there throughout the text, and has also made several important additions. These are always characterised by their practical value, and form a valuable accretion to the French text. They are printed in italics, so that the reader can readily see what Professor Jadassohn has added. It must have been no easy task to make these additions, for it is to be remembered that this work is somewhat elementary, and it was not intended to be anything approaching a complete treatise; he has exercised a wise restraint in keeping his remarks within bounds so as not to alter the character of the work. In some cases the addition is only a word or two, in others it consists of a paragraph. It may be mentioned that Dr. Darier has approved of these additions, and also that they are never really written from the standpoint of a critic. Dermatologists who are readers of German will be fortunate in possessing this valuable German translation.

Diet in Health and Disease.

By JU[illegible], and JOHN RUHRÄH, M.D. [illegible] revised and enlarged. London [illegible] B. Saunders Company. 1913. Pp. [illegible] Price [illegible] net.

THE fourth edition of this (now) comprehensive work shows considerable extension in several directions consistent with the development of modern ideas on the subject. The previous edition was reviewed in our columns just four years ago, when we expressed a favourable opinion of it because it appeared to us that not only had the authors succeeded in giving a clear presentation of the practical side of the subject, but that they had taken care also to keep their readers in touch with the latest interpretations of those physiological researches that bear upon purely dietetic questions.

The present edition fully maintains this character. Recent physiological advances have necessitated the addition of a section on the mechanism of digestion and the rewriting of a chapter on metabolism and the prescribing of diet. The analytical tables have [illegible] questions. Again, the articles on diabetes and gout show a treatment of the subject fully in accordance with modern research and expressions of opinion. All through we find that a strong attempt has been made to lift the subjects out of old empiricisms. The book shows a thoroughness of treatment and compilation which should render it a real help to practice and a valuable source of reference generally on the science of food.

MISCELLANEOUS VOLUMES.

"THEN, all of a sudden, I wondered if the man of the present day could leave all his luxury behind him and go back into the wilderness and live on what nature intended him to have." And Joseph Knowles, an American painter—being imbued with the spirit of John Hunter, who wrote to Jenner, "Why think? Why not try?"—selected a forest wilderness in the North-West Maine country, known as the Dead River Region, where on August 4th, 1913, accompanied by a number of friends as far as the foot of the Spencer Trail, which rises straight up the side of the Bear Mountain, he smoked his last cigarette, undressed to nakedness in the drizzling rain, waved farewell to all human [illegible] and struck out alone along [illegible] elter, weapons, implements, [illegible] On October 4th he emerged from the Canadian forest on the shores of Lake Megantic, having lived the life of a primitive man for two months in the wilderness of Northern Maine. He wore the skin of a black bear, his legs encased in crudely tanned deerskin chaps, with the hair inside, his feet in moccasins of buckskin, and carried on his back a pack made from woven lining bark of the cedar, holding various implements from the forest. He had a rude bow and arrows and a crude knife made from the horn of a deer; [illegible] The story of what passed [illegible] wilderness, his first adventure, [illegible] mental and the physical man, and much of interest concerning his neighbours of the wilderness and his animal studies, trapping and woodcraft, and the excellence of the training of the boy scouts is to be read in *Alone in the Wilderness*, by JOSEPH KNOWLES (London: Longmans, Green, and Co. 1914. Pp. 296. Price 5*s.* net.). Not the least interesting feature of the book is the reproduction of sketches made in the woods on birch bark with burnt sticks from his fires.——Those venturesome people who enjoy risking their necks mounting climbing—and the mountain seems no longer to inspire the awe it once did—will find much to interest them in *How to Become an Alpinist* (London: T. Werner Laurie. Pp. 218. Price 6*s.* net). In the first place it is written by one who knows what he is talking about, Mr. FREDERICK BURLINGHAM, for has he not kinematographed the Matterhorn? Then it is pleasantly and racily worded with a fund of humour which reaches its highest point in the final chapter, "How to get Killed on the Alps." The humour here, by the way, is put to a distinctly useful purpose, for it is likely that the warnings thus conveyed will stick more in the amateur's mind than if they had been given with solemn gravity. Instruction is given as to choosing an alpine centre, equipment and training and excursions for beginners. Some famous women alpinists receive a chapter. The training of guides is described and the causes of accidents are discussed. Finally, various alpine localities are described, and we would call vigorous attention to the St. Bernard Hospice, particularly to note that 20,000 tourists have annually visited the hospice for years past, when "no charge whatever is made for either food or lodging, and the only request is that the key be left on the chamber door on parting." Mr. Burlingham properly pillories the meanness of those who abuse this magnificent hospitality by slinking off without putting even enough to pay for their food in the chapel offering box, so that the total contributions of this horde of sightseers have scarcely sufficed to feed one-twentieth of their number.——In the second edition of *Mentone as a Health and Pleasure Resort*, Dr. D. W. SAMWAYS has made large alterations in the text, necessitated by the great progress that has taken place in the town since the first edition appeared in 1901. The little book, which b[illegible] imprint of W. T. Southwood and Co., printers, Exete[illegible] contains much interesting [illegible] as well as a description of the modern town and its climate—viewed in the light of experience, of geographical considerations, of the local [illegible] of its meteorological features and statistics. [illegible] and pastimes, and drive[illegible] of travel to and from the place. We must not omit to mention the clever sonnet "To My Mosquito," by "Adrian Ross."

That the importance of proper training of and provision for the feeble-minded has greatly taken hold upon the public conscience is evidenced by the Mental Deficiency Act. Methods of training suitable for this class of people will doubtless be called for as a consequence. For those directly interested in the matter a little book for teachers, entitled [illegible] of the works at Darenth Industrial Colony [illegible] and Imbecile Patients of all ages, will doubtless be found useful. Among the trades that are taught at Darenth are carpentering, bookbinding, envelope and box making, brush and [illegible] and tailoring and wool rug making [illegible] building, and upholstering, [illegible] there is a wide range suitable for various classes of persons. The book is illustrated with half-tones representing the classes at work in the various industries.——*Experience Teaches* (London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. *1914. Pp. 194.* Price, cloth 2*s.*; leather 4*s.*), by IVON TRINDA, is a volume of discursive remarks containing advice, partly to youngsters and partly to their parents and guardians, on school and what to learn, business, married life, recreation, and things in general, with some irrelevant anecdotes. The author urges teaching the boy to work with his hands [illegible] for the blessing of tobacco, [illegible] "display [illegible] and superiors, to manners, customs, habits, [illegible] ancient buildings"; has much that is sensible to say on fresh air and ventilation, the curse of drink, fads, the social vice and its consequences, and not a little that is otherwise on vivisection. We must confess that the mental attitude of a man—obviously a medical man—who catalogues as *admitted achievements* of animal experimentation the discovery of the circulation, the antiseptic treatment of wounds, the rendering possible of brain surgery, chloroform anæsthesia (partly), the clinical thermometer, much of physiology, and the action and dosage of many valuable drugs, and yet asserts that "much of the vivisection conducted nowadays will never have very much bearing on 'research into causation and treatment of disease,'" is to us incomprehensible.——Another little volume of semi-medical essays, four in number, with an introduction, is *The Road to a Healthy Old Age* (London: H. K. Lewis. 1914. Pp. 104. Price 2*s.* 6*d.* net), by THOMAS BODLEY SCOTT. The last essay is a brief outline of the preparation and action of vaccines; the other three are more discursive, discussing fatigue and cheese and wine and galvanism and various aspects of the metabolic class of diseases which are mainly the results of deficiencies in personal hygiene.

JOURNALS AND MAGAZINES.

Annales de Médecine.—Our French *confrères* have grasped one of the inconveniences of the modern tendency to specialisation—that is, the increasing segregation of important original communications in special journals, whereby the difficulty of keeping pace with at least the broad outline of evolution in medicine is greatly augmented. The proportion of these special medical journals to general ones is perhaps more excessive in France than elsewhere. To help in remedying this position a new monthly journal for readers in the French tongue has recently been published under the auspices of Professeur Agrégé Léon Bernard, Dr. Fernand Bezançon, Dr. Georges Guillain, Dr. Marcel Labbé, Dr. Edouard Rist, and Dr. Gustave Roussy. It is called the *Annales de Médecine*, and the first issue, dated January, 1914, lies before us. It will embrace all fields of medicine, both clinical and experimental, and while it particularly aims to represent the progress of French medicine, its pages will not be closed to foreign writers. Besides original communications it will contain the now customary review of current progress, not merely confining itself to presenting an abstract of the work published elsewhere, but rather critically appreciating, at the hands of a competent reviewer, the value of the communication. The present number contains original communications by Professor A. Chauffard on the pathogeny of congenital hæmolytic icterus; Professor Pierre Marie and Dr. J. Lhermitte on the lesions of chronic progressive chorea; Dr. Paul Ravaut on the detection of the preclinical manifestations of nerve syphilis; and M. Rubens Duval on the histologic method of defence of the organism against cancer. The critical review concerns itself with a consideration by Dr. Fernand Bezançon and Dr. S. I. de Jong of recent communications bearing on infectious pleuro-pulmonary congestions. The journal, which is published by Masson et Cie, Paris, the subscription to countries within the Postal Union being 23 francs, is of convenient size, well printed, and is illustrated with admirable coloured plates and half tones. It promises to form a welcome addition to serious medical periodical literature.

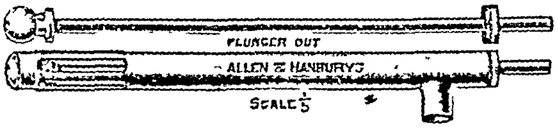
Jahreskurse für ärztliche Fortbildung. Munich: Lehmann. Price 18 marks.—In the January number of this useful summary of the modern point of view in German medical literature Professor Schwarz writes on the Nature of Eosinophilia. He points out that under this heading we must include eosinophilia of the blood and also of the tissues. The condition is a specific reaction of the blood-forming elements in the sense that the eosinophile cells may rise or fall independently of the other leucocytes. It is probably the reaction to a special chemical stimulus. The various clinical conditions giving rise to eosinophilia are then passed in review, beginning with bronchial asthma, in which there is eosinophilia both of the blood and of the bronchial connective tissues, due probably to anaphylaxis. Other causes are worm-infections, skin diseases, and after acute infections; the relation to the secretions of the ductless glands is also reviewed. Professor Lubarsch follows with a discourse on what modern German literature calls *Nachkrankheiten*, which we might translate as "Afterwards-diseases," including tabes or general paralysis following upon syphilis, or gall-stones after typhoid fever. He then writes of some of the problems of cancer, such as precarcinomatous conditions and metastases, pointing out how in the skin cancer supervenes upon a scar, in the stomach upon an ulcer, in the liver upon cirrhosis, in the gall-bladder upon gall-stones. The rôle played by parasites is briefly discussed—for instance, certain nematodes of the rat's stomach produce an epithelial proliferation like cancer. The tissues of the body have a variable resistance to secondary infection, but the writer does not seem to know Sampson Handley's important researches on cancer dissemination. The article concludes with a few remarks on regeneration and transplantation of tissues.

Dental Record.—The March issue contains a paper by Dr. A. A. Mumford on the Oro-nasal Cavities during Adolescence, in which the author gives the results of his investigations into the oro-nasal cavities and acuity of sense-organs in 1000 boys at the Manchester Grammar School. Mr. Spiller, in a note on the Movement of the Premolars, states that the maxillary teeth tend to rotate, the internal cusp in the case of the first premolar moving forwards, and in the case of the second premolar backwards. In the mandible the premolars tend to tilt backwards. Some amount of rotation is, however, often present, and is usually in the opposite direction from that seen in the maxillary teeth. A paper on A Public Dental Service is communicated by Mr. T. Mansell, and there is a short note on the Nerves of the Hard Substance of the Teeth by Mr. G. W. Watson.

New Inventions.

AN INTRA-UTERINE DOUCHE.

THE accompanying diagram represents a douche which I have found very satisfactory in maternity work. The large size of the channels permits of a copious flow of lotion and an easy unobstructed return. I have frequently given a couple of gallons of lotion in a few minutes. If the return should be *partially* blocked by a large clot (I have never found it completely blocked) the inner portion of the instrument can be easily withdrawn without removing the douche as a whole from the uterus. The blunt end is an ample safeguard against perforating the wall of the uterus.



The instrument is manufactured for me by Messrs. Allen and Hanburys, 48, Wigmore-street, W.

Derby. R. DOUGLAS LAURIE, M.B., Ch.B. Edin.

THE GENERAL HOSPITAL, BIRMINGHAM.—The annual meeting of the governors was held on March 18th, under the presidency of Lord Hampton. The board of management reports that the number of in-patients under treatment last year was 5908, an increase of 411, the daily average of patients being 319·5, an increase of 5·25 daily. Of the in-patients 1079 were children under 12 years of age, of whom 272 were under 2 years. During the past year there have generally been over 180 cases on the list waiting admission. The number of out-patients was 58,815, a decrease of 8502. 4317 operations were performed, as compared with 3899 in 1912. The total income during 1913 was £31,990 2*s.* 9*d.* The amount from subscriptions was £7210 2*s.* 9*d.*, or £224 less than in 1912. Ordinary donations were £404 3*s.* 3*d.* £12,995 were placed to the credit of the current account as the moiety of legacies received during the year. The total expenditure was £30,482 10*s.* 3*d.* The deficit at the end of 1912, £7745 9*s.* 4*d.*, has been discharged, and there remains a balance in hand of £132 8*s.* 7*d.* Attention was called to the urgent need of increased accommodation. Before the Insurance Act came in a waiting list of 90 patients was regarded as large; now it was usual to have 180 to 200. It has been decided to open a ward which has been kept fallow for use in case of a serious disaster. The board reports with regret that no single subscription has been given to the hospital by the Insurance Committees or by Approved Societies under Clause 21, and only ten contributions have been received from societies towards the maintenance of in-patients who had no dependents. The total sum received has been £13 7*s.* 11*d.* towards the cost of maintenance of about £77 for the patients in question. The work of the X ray department has increased greatly; 3850 radiographs were taken in the year and many more patients were "screened," and 285 were treated with 2808 applications by X rays and radium.

The Blood-forming Power of Sanatogen as evidenced by the Percentage Increase in Haemoglobin and the Count of the Red Blood Corpuscles.

Medical literature, during the last few years, has recorded many specific instances of the remarkable blood-forming power of Sanatogen.

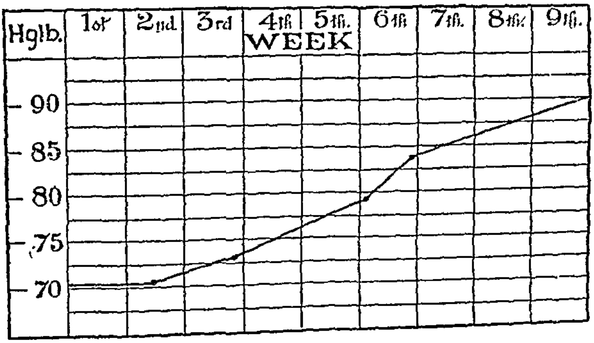
A striking illustration of this fact is furnished in the accompanying diagram, based on observations made by Dr. Starkloff, of the Consumption Sanatorium, Belzig, and published in *Zeitschrift fur Tuberkulose*, No. 6, 1911.

The diagram shows the average increase in the hæmoglobin content of the blood during nine weeks, based on the analyses of thirteen patients.

It proves that during the whole period—from the middle of the second week, when the influence of Sanatogen began to make itself felt, until the end of the ninth week, when the administration of the preparation was discontinued—there was an uninterrupted rise in the hæmoglobin value from about 71 per cent. to 90 per cent., or, roughly, 20 per cent. for the period.

AVERAGE HAEMOGLOBIN INCREASE

from Observations made by Dr. Starkloff at the Consumption Sanatorium, Belzig.



Conclusive as is the evidence furnished by the diagram, its importance is considerably emphasised by similar results recorded in English periodical literature.

Thus, in *The General Practitioner*, the author of an article records the following cases: (1) A girl of 17 was suffering from right supra-orbital neuralgia of considerable intensity. The red corpuscles numbered 3,900,000 per c.mm. and the hæmoglobin value was 40 per cent. She took Sanatogen for twenty-one days, when her red corpuscles numbered 4,200,000 per c.mm. and the hæmoglobin had risen to 56 per cent. She made a quick recovery.

(2) A fair-haired girl, aged 12, suffering from a fourth attack of chorea, showed red corpuscles numbering 3,600,000 per c.mm., with hæmoglobin 49 per cent. At the end of a month the red corpuscles numbered 4,500,000 per c.mm., the hæmoglobin 55 per cent. and the choreic movements had entirely disappeared.

Again, in *The Medical Press and Circular*, the writer of an article records this case:—

A woman, suffering from melancholia, who took to her bed after sustaining a severe shock from the sudden loss of her favourite child, showed red corpuscles numbering 3,800,000 per c.mm., with hæmoglobin 48 per cent. At the end of a fortnight's treatment with Sanatogen, her red cells had risen to 4,000,000 per c.mm. and hæmoglobin to 52 per cent. Her mental equilibrium was restored and she was able to resume her home duties. The physician recording the case states: "The improvement in this case was most striking and suggestive."

A. Wulfing & Co., London, Berlin, New York, Sydney, Cape Town, Shanghai, Bombay.

In this respect there is probably a good deal of truth in the strictures made by the report, but the allocation of the blame is difficult. An enormous amount of additional labour has been cast by the Insurance Act upon local bodies, and upon those persons who are prepared strictly in the public interest to devote themselves to work upon such bodies. Financial considerations press heavily when public work on a large scale has to be undertaken, and in the administration of the Insurance Acts inadequate medical representation has, no doubt, had an effect more likely to be felt with regard to the treatment of tuberculosis than in anything else. The report of the Research Department of the Fabian Society on this matter is likely to produce useful discussion upon the topics treated in it, and if it is to some extent pessimistic in its conclusions, it is the temperate and considered judgment of persons competent to criticise, and is commendably free from the more marked prejudice and partisanship which characterise so much of the praise and blame which the Insurance Act has provoked. It is to the credit of the committee that they have avoided nebulous criticisms of the scheme as a whole, and have limited their task to the scrutiny of ways in which improvements can be effected in the working of the Act as it now exists.

◆

Eyes for the Blind.

THE KING accompanied by the QUEEN opened the new premises of the National Institute for the Blind in Great Portland-street, London, on Thursday of last week. A considerable crowd of blind people assembled in the streets without, while within the entrance hall of the institute was a blind guard of honour, and the welcoming address was read from Braille text without a moment's hesitation by Dr. A. W. G. RANGER, the blind chairman of the institute. The publicity given by the gracious action of the KING and QUEEN to the needs of what was formerly the British and Foreign Blind Association will have an outcome, we hope, in the shape of generous subscriptions from the public; our readers can bring before their patients and friends no worthier object of endowment than the National Institute for the Blind.

The institute was founded in 1868 by the late Dr. T. R. ARMITAGE, who was himself blind, and since that time it has printed and distributed a large number of books of all sorts in embossed or Braille type. These publications form veritable eyes for the blind, now that they are becoming numerous and that even a certain number of magazines are reproduced in this way. Few blind people are so fortunately placed that at all times they can obtain the help of the spoken word, but when this fails them their want of eyes can be made good to some extent by the use of Braille literature. But unfortunately the supply of books published in Braille type is at present very limited. The publications, by reason of their great bulk and the tedious and complicated processes of manufacture, can only be produced at a vast cost. "Pickwick" requires 14 volumes and costs £2 5s.; "David Copperfield" is in 10 volumes; "Uncle Tom's Cabin" in 8; "Kenilworth" in 7; "Sherlock Holmes" in 6; "Jane Eyre" in 5; "Midshipman Easy" in 4; and the cheapest of these famous works is 12s. Give the blind people books which they can be easily taught to read and they will do much to equip themselves for the battle of life, and enjoy themselves much more as their fellow men do. To the address of welcome the KING made a very sympathetic and indeed eloquent reply. He rejoiced with the managing committee of the institute that their work, which has brought solace and hope into many lives, should have met with such a response that the enlargement of its scope must follow, and while wishing them all success in their efforts to benefit a large number of their afflicted brethren he added the just remark: "It is a commonplace that men do not realise the value of that which they have never lost, but I am confident that your appeal for funds to extend and develop your undertaking will stir the imagination of many who unreflectingly enjoy the blessing of sight."

Following on the KING'S visit there has come the Mansion House Fund on behalf of the National Institute for the Blind, one of the main objects of which is the cheapening and amplifying of literature of every description for blind readers. The LORD MAYOR of London in the appeal states that there is an immediate need for £30,000 to complete and equip the buildings inaugurated by the KING and QUEEN, while it is hoped that a further sum of at least £100,000 will be secured to form an adequate maintenance fund which will go towards reducing the excessive cost of the bulky Braille volumes which form the library of the blind. The number of books which have been done into Braille is not yet large, and the choice of books for this treatment seems on perusal of the catalogue to be extraordinary, but it is a matter of fact that books of any sort are a blessing beyond all calculation to blind people. There is nothing whatever we can do for blind people that compares for one moment with the boon of placing within their hands that great medium for the interchange of thought and idea, the printed book. The catalogue of Braille books to be obtained from the National Institute for the Blind contains, in addition to primers for children, historical readers, elementary grammars and dictionaries, and certain recognised works on mathematics and science, a selection of fiction, poetry, drama, and a good number of religious and devotional books. Money is urgently required to add to the number of books printed in Braille type, and we add our voice to Mr. C. A. PEARSON'S who pleads this cause in THE LANCET this week. We beg our readers to use all their influence with the public in behalf of the blind.

The Election to the Council of the Royal College of Surgeons of England.

From the names of candidates for election to the Council of the Royal College of Surgeons of England next June, which we have been able so far to announce, it will be seen that the contest will be an interesting one, nor is it necessary to conclude that the list is yet full. The candidates so far in the field represent the medical school of the University of Manchester and the metropolitan medical schools of the Westminster Hospital, St. Bartholomew's Hospital, King's College Hospital, University College Hospital, Charing Cross Hospital, St. Thomas's Hospital, and St. George's Hospital. Every one of the candidates for one reason or another can expect the suffrage of a certain number of Fellows. Mr. Thorburn has in his favour, in addition to other unmistakable claims, the fact that the retirement of Mr. Richardson Cross leaves a seat vacant on the Council for a provincial member. There is no recognised percentage of these members, but the opinion that the provinces should be well represented is general. Mr. Cross's vacancy, however, is strongly challenged by Mr. J. B. Lawford, ophthalmic surgeon to St. Thomas's Hospital, standing as an ophthalmologist for the seat of a retiring ophthalmologist. Mr. McAdam Eccles will have to reckon with the feeling that St. Bartholomew's Hospital is already thoroughly well represented on the Council. Mr. W. G. Spencer, Mr. H. S. Pendlebury, Mr. F. F. Burghard, Mr. Raymond Johnson, and Mr. Stanley Boyd are all sure of receiving the support of many Fellows who know the high character of their professional and educational work. The Westminster Hospital has been without a representative on the Council for some time, and the regretted death of Mr. Clinton Dent has left St. George's Hospital without a voice. Only one member of the staff of King's College Hospital is now on the Council, and there is no representative of Charing Cross Hospital at all, but there are two representatives from University College Hospital. Mr. P. Macleod Yearsley is well known as the chairman of the National Bureau for the Promotion of the Welfare of the Deaf.

We may say at once that we do not regard it as particularly important that all the metropolitan medical schools should be represented on the Council of the College, for we do not picture the Council as occupied in maintaining the claims of one school against another. There was a time when a spirit of this kind may have prevailed, but time has removed what used to form a serious abuse. We believe that the Fellows, also, are far more willing to give their votes with a sense of public spirit than used to prevail even in comparatively modern times. It is generally desired by the Fellows to choose the best man among the candidates. Indeed, we have reason to believe that there are two classes of candidate for the Council of the College who at the present juncture would be supported by many Fellows, though a few years ago their chances of election to the Council would have been very slender. No candidate from these classes has as yet decided to put his name forward, but a Fellow of the College engaged in general practice or a Fellow of the College holding some big public health appointment would either of them prove a strong candidate. The deliberations of the Council might be much strengthened by the presence at their board of men who have particular opportunities for understanding the relations of the medical profession to the public in the matters of ordinary social or municipal life. There is no suggestion that the presence of a medical officer of health, of a medical officer for educational purposes, or of a Fellow in general practice upon the Council of the College, would be considered as any answer to the demand, which we have so often supported in these columns, for some measure of reform which would give the Members of the College a share in the government of their body. It would not be regarded as such an answer in any general way, but it would give the Members a sense that they were obtaining a closer measure of representation than before. Anyhow, the most ardent advocates for the alteration of the constitution of the College could see nothing but good as likely to arise from the introduction upon the Council of a Fellow engaged in general practice, or of one holding an appointment which brings him daily into personal touch with general practitioners. We believe also that the presence of such a Fellow on the Council would be welcomed by those in authority at the College, who would see the profit to be derived from the intimate information thus placed at their disposal. There are not many Fellows holding public health appointments, so that the appearance of a candidate for the Council from among them is not very probable; but the Fellows in general practice are now a large body, and we should be very pleased to see one offer himself for a seat on the governing body of his corporation. There still remains some time during which the claims of such a Fellow could be considered by the constituency, if the name was set down at once.

We had nearly said that time remained for the organisation of such a candidature, but organisation implies canvassing, and so far from suggesting that there should be any regular canvassing for seats upon the Council of the Royal College of Surgeons of England we feel strongly that any procedure of the kind is quite wrong. The governing body of the College ought to be selected very carefully, votes being given with due regard to the work and standing of the candidates, and personal claims being set aside as far as possible. That a man should vote for the candidate whom he believes in personally is not only natural but safe, for the candidate who obtains a successful measure of support of this kind must be a very strong one.

Votes given in response to knowledge of the good work done by a candidate are also rightly given, but such good work should be susceptible of public test and not merely vouched for by the candidate's friends. Lastly, votes given "to oblige" are vicious in elections to such bodies as the Council of the Royal College of Surgeons of England.

Annotations.

"Ne quid nimis."

INFANT MORTALITY AND THE WELFARE OF INFANCY.

The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy is memorialising the General Medical Council with the hope that the authorities of medical education may raise the standard of their requirements as to the knowledge shown by students in the subject of infant hygiene. We view with considerable apprehension any suggestion to increase the scope of the examinations which the medical student is required to pass, inasmuch as it is allowed on all hands that the present curriculum is either overloaded or ill-arranged, as the time taken by the average candidate to obtain a degree or diploma is already over six years; but infant hygiene is a subject of the first importance to all practitioners, as well as one of overwhelming practical interest to the State, and from this point of view Sir Thomas Barlow, the chairman of the executive committee of the association, and his enthusiastic colleagues are justified in the action which they are taking. Moreover, it is demanded by the following resolution which was adopted at the English-speaking Conference on Infant Mortality held in London on August 5th, 1913:—

> That this conference requests the executive committee of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy to communicate with the General Medical Council and the degree and licence-conferring bodies, with a view to infant hygiene being given a more important place in the medical curriculum.

The executive committee of the association, in carrying out the above instruction, prepared a report upon the whole subject which shows that the various teaching centres are not unwilling to provide the requisite instruction. They have made inquiries of all the medical schools and children's hospitals where teaching is given throughout the United Kingdom, 51 in number, as to present or proposed facilities for the teaching of infant hygiene, and have received replies from 27 of these institutions. "In four cases," says the report, "viz., Manchester, Glasgow, Dublin, and Belfast—a course and certificate of special attendance and instruction are required. In six cases—viz., Guy's, Middlesex, St. Bartholomew's, Westminster, King's, and University Hospitals, London—there is a special department or course of instruction in this subject. At the Royal Free Hospital for Women, London, a weekly infant clinic is to be opened this year. At two special hospitals—Evelina and Great Ormond-street, London—as at the West London Hospital and other hospitals without medical schools, and in the comprehensive course held annually in London under the National Association for the Prevention of Infant Mortality, special instruction is given to graduates." In the remaining medical schools returning replies, instruction is considered to be given in the general curriculum of the hospital, sometimes by the physicians, sometimes by the surgeons, sometimes by the obstetricians and gynæcologists, and sometimes by lecturers on general hygiene. It is this assumption that instruction in infant hygiene is already being given that makes us feel particularly sympathetic towards a movement the wisdom of which must otherwise have been challenged on the simple ground that to ask a student, already overburdened, to carry another weight was injudicious. But it is a question whether the student is being asked so much to carry another weight as to have those which he is now carrying arranged in a manner more convenient to the porter. The recommendations of the executive committee are as follows:—

> That degree and licence-conferring bodies should require from each candidate for the final examination in medicine a certificate of having attended a course of clinical instruction on infant hygiene, to include lectures or demonstrations on the management of infants, and the prophylaxis and treatment of infantile diseases.
>
> Such a course should include instruction in the part played by the State in infant hygiene, with special reference to the duties and functions of the medical practitioner, the midwife, the hospital and local sanitary authorities, and the health visitors.
>
> The certificate required from candidates in midwifery for the final examination should include evidence that they have received instruction in antenatal pathology and hygiene, and in the management of infants during labour, the puerperium, and the period of lactation.

We agree with the executive committee in thinking that the machinery for such a course of instruction already exists in most of the leading centres of medical education, and that the rearrangements which could be effected by a little organisation would lead to most medical students receiving the instruction outlined in the recommendations.

TONE IN RELATION TO SHOCK.

The lecture delivered by Mr. Rendle Short,[1] in which he directs attention to the possibility of loss of muscular tone being concerned in the causation of shock, offers another instance of the increasing attention which is being directed to this matter of tonicity. There is little doubt that it constitutes a function of elemental and fundamental importance. Though the slight degree of resistance to full relaxation of muscular elements looks to be of trivial significance, the fact that prominent cerebral centres concern tonic activities, as represented for skeletal tissues by the cerebellum, and for visceral structures by the corpus striatum, indicates that wider functions are to be expected than this relatively simple mechanical action. Developmentally, tonus had a dominant representation in contractile elements. Before an integrating nervous mechanism enforced the value of concerted and graded movements, this power of automatic contraction was the simplest defensive mechanism possessed by the lowest organisms. Though this simple response has long since been superseded by skeletal organisation, its impress upon such organisation is increasingly recognised, as Sherrington's work shows. It is a quality, for example, which is capable of reinforcing skeletal activity to a remarkable degree, and this it does at no sacrifice to the delicacy of such activity. And just those influences, included by the psychologist under the term affective states—

---

[1] The Lancet, March 14th, 1914, p. 731.

fear, anger, love—which are most elemental or preservative in character, are just those most capable of affecting tone. Developmentally, this is what one would expect, for they are intimately related to the safety of the individual, and tone had its origin in this relation. The brain centres, too, for controlling tone are of older origin than the later refinements. If skeletal structures appear to show little active evidence of tone, X ray observations upon the gastro-intestinal tract have emphasised the significance of tone as an entity and as a quality which is independent of peristalsis. And the later cardiac work has again shown the importance, not only of the quality of tone but also, similarly to the gastro-intestinal tract, its independence of other functions. In both these spheres tonicity is a quality to be considered as a definite, though at present ill understood, entity. In the nervous system the quality of tone naturally assumes a complexity which at present baffles definite assertion. The relation of the cortex to the cerebellum and central nuclei shows an intimate and coördinate arrangement which one would be led to expect from the study of the skeletal system alone. But the complex relation to the affective states is more difficult of solution, though the intimacy of relationship would be anticipated from developmental views. It is reasonable to suppose that the state of shock would find wide representation in changes of tone concerning visceral as well as skeletal and cerebral function, and investigation along such lines offers a promising field of inquiry.

COORDINATION OF THE TREATMENT OF MENTAL DEFECT IN LONDON.

THE London County Council has decided that the Mental Deficiency Act, 1913, shall be administered (if Parliament permits) by a committee which shall also be responsible for the control of the insane asylums, and application is being made to Parliament this session for power to deprive the Asylums Committee of its special powers and independence under the Lunacy Acts and to merge its duties in those of the new committee required to be set up under the Mental Deficiency Act. In the meantime the Committee for the Care of the Mentally Defective and the Asylums Committee will consist practically of the same persons, but the two branches of work will be kept distinct. The General Purposes Committee, reporting to the Council recently on the organisation of the service for the care of all kinds of mentally defective persons, intimated that when the temporary arrangements indicated above came to an end the Council would probably be invited to place the general supervision of the arrangements for the treatment of persons under the Mentally Defective and Lunacy Acts in the hands of one officer. This would only be the natural corollary of the Council's decision to combine the two services with a view to coördinating the treatment of all persons suffering from mental defect. At present there is no one person occupying the position of a chief professional or executive officer in the asylums service. There is a clerk or administrative officer, and each asylum is superintended by its own professional or executive head. For the interim period, pending a decision by the new committee when it was in possession of full powers, the professional and executive work, so far as it had reference to the Mental Deficiency Act, should be controlled, in the view of the General Purposes Committee, by the medical officer of health for the county, the arrangements for the asylums work being continued as at present for the time being. No doubt a large proportion of the persons to be dealt with under the Mental Deficiency Act would be ascertained by notification from the schools, and the new Act appeared to the Committee to require a continuous medical action from the first stages during childhood to the stage of certification for institutional treatment or guardianship. The officer upon whom it would devolve in the great majority of cases to select children for notification to the Committee for the Care of the Mentally Defective is the medical officer of health in his capacity of school medical officer, so that his appointment as suggested would be in accordance with the intention of the Act. The Council approved the report, but decided, after discussion, to call the new body the Asylums and Mental Deficiency Committee.

THE PASSING OF THE DOCTRINE OF AERIAL INFECTION.

IN the *Journal of the American Medical Association* of Feb. 7th Dr. C. V. Chapin has published a very cogent article showing how erroneous is the time-honoured view that the air is the chief vehicle for the conveyance of infectious disease. In the 1883 edition of Parkes's "Hygiene," the standard book of the day, malaria and yellow fever were considered typically air-borne disease. Typhoid fever, cholera, dysentery, and diarrhœal diseases were said to be largely air-borne, and sewer air was alleged to be an important factor in their production. Typhus fever and plague were thought to be spread by a vitiated atmosphere. It was assumed that bacteria were freely given off from fæces, urine, and other discharges, and were exhaled in the breath. However, in the late "seventies" of the last century Nageli and Buchner showed that bacteria are not given off from moist surfaces or liquids in a state of rest, and Tyndall demonstrated that expired air is sterile. The discovery of the tubercle bacillus by Koch led to the view that the usual mode of infection was transmission on particles of floating dust. The investigations of Cornet, who showed in 1885 the presence of tubercle bacilli in dust, confirmed this view. In 1897 Flugge showed that bacteria could be carried in the fine droplets of saliva thrown out from the mouth during loud talking or coughing. It had previously been found that bacteria-holding droplets could be thrown into the air by agitation of sewage. But unwarranted inferences were drawn. Because Cornet's guinea-pigs were infected by clouds of tuberculous dust and Flugge's guinea-pigs when held a short distance in front of a coughing consumptive, it did not follow that dust or droplets are under natural conditions the chief mode of infection. The question of dosage in causing disease is all-important, but has been much neglected in bacteriological work on aerial infection. One observer found bacteria only four times in 200 litre samples of air from the soil-pipes of Boston sewage, and then only when splashing of sewage occurred at the place and moment of examination. Later experiments were made to determine the extent to which general air infection in an apartment is caused by droplets. In 140 litres of air taken at various points from a room immediately after from 10 to 50 minutes' loud speaking by a person whose mouth was infected with B. prodigiosus, the organism was found only seven times. In 74 litres examined for streptococcus salivarius none were found. More recently the air of New York schools was examined for the acid-forming streptococci which are the most abundant organisms in the human mouth. In 30,000 colonies isolated from 750 plates only 10 mouth streptococci were found. On the other hand, he found salivary bacteria in the dust of schoolrooms in enormous numbers. To turn to the clinical aspect of the question. A little after the middle of the last century, under the great authority of Murchison, it was believed that the chief cause of typhoid fever was effluvia from decomposing animal matter. When the Prince of Wales in 1871 contracted typhoid fever at Sandringham the escape of sewer gas into his apartment was considered by everyone a sufficient explanation. Now conveyance by infected water or food is universally held, and the "carrier" has supplied the missing link in previously inexplicable cases. Cholera, dysentery, and diarrhœa were considered to be largely spread by air polluted with the discharges of patients. The discovery and study of the causal microbes has shown that it is by water, food, contact, flies, and carriers that these diseases are spread. Pasteur showed the importance of particles floating in the air as a cause of putrefaction. In applying his discoveries Lister tried to prevent infection of wounds from the air by means of the carbolic spray until he found the unimportance of this source. Pyogenic bacteria can always be found in the air of operating theatres, but they rarely cause wound infection, probably because of their small number and the diminution of virulence by drying and exposure to light. A wider infection of the atmosphere has been claimed for small-pox than for any other disease, but Dr. A. Collie in a recent book on "Small-pox and its Diffusion" has shown that the alleged aerial conveyance around hospitals is probably due to personal contact. The belief that scarlet fever, diphtheria, measles, and whooping-cough are air-borne is being abandoned by many observers.

NEPHROPEXY FOR MOVABLE KIDNEY.

THE discussion at the Surgical Section of the Royal Society of Medicine on the surgical treatment of movable kidney[1] was of considerable practical importance, if only for eliciting the divergence of opinion as to the amount of success which is likely to follow such procedure. The condition itself is one in which the limits of health and disease are very indefinitely marked, as it is undoubted that in many apparently healthy persons a much greater range of mobility is possessed by the kidney than is usually recognised as normal, while the disturbances which are associated with some instances of such increased mobility are not easily explicable as direct consequences of the condition. Again, the range of movement is not by any means proportional to the severity of the symptoms. These are often, or indeed usually, of a neurasthenic nature, and may not be associated by the patient with the kidney or its neighbourhood until attention is called to the abnormality as a result of medical examination. On the other hand, there is another group of cases which present features more definitely referable to traction in the renal region, the pain and discomfort being relieved by rest in bed and reproduced by movement and assumption of the erect posture. It would seem, then, that on scientific grounds operation is indicated in the latter group and to be avoided as far as possible in the former, and experience seems to bear out this view. In neurasthenic cases the question of nephropexy may have to be faced as a last resource, if the patient has become imbued with the fixed idea that the movable kidney is the source of trouble and that fixation is the only means of relief, but in such persons a large percentage of failures must be expected. The actual mortality of the operation of nephropexy is very small, perhaps 1 per cent., and it presents no particular difficulties. It is probably well to aim at a high point of fixation, and attachment to the twelfth rib gives good results. There is, however, little doubt that the operation is now less in favour than it was some years back, and that the general direction of opinion is towards restricting the number of cases so treated and relying rather on general measures of hygene and on carefully adjusted abdominal support.

TROPICAL SANITATION AND HYGIENE.

THE syllabus of the new course in tropical medicine and hygiene at the London School of Tropical Medicine has now reached us. Two courses, commencing on May 1st and Oct. 1st, and extending over a period of eight weeks each, will be given annually. There will be ten lectures and demonstrations on medical entomology by Colonel A. W. Alcock, I.M.S., these including the common tropical insects that carry disease. Three lectures and two demonstrations will be given on port hygiene by Dr. H. Williams, eight lectures and demonstrations on bacteriology by Professor R. Tanner Hewlett, and a practical laboratory course on bacteriology by Dr. B. H. Wedd. Professor W. J. Simpson will deal with hygiene in the tropics and public health subjects—town planning, building laws, insanitary areas and houses, nuisances and infectious diseases being included under this heading. Dr. C. M. Wenyon will give four lectures and demonstrations upon protozoology, and Dr. R. T. Leiper the same on helminthology. Elementary surveying and sanitary engineering will be under the charge of Mr. S. F. Corby, while finally, Dr. Arnold Chaplin will instruct the students on the care of the sick on board ship in the tropics. It is intended to make the course as practical as possible, and to illustrate the application of the methods taught in the investigation of disease by material obtained from the hospital adjoining the school. The course will thus be seen to be a very comprehensive one, and one of real value, as it will teach the young men of the present day the application of the careful research work carried out in the last 15 years by so many of the pioneers of tropical medicine. A great advance has taken place in recent years in the health of all the tropics, and especially in the more deadly parts such as the West Coast of Africa, and it behoves the present generation to keep this advance up and to do still better. Many of the villages and stations in the tropics at the present day are in the sanitary condition of English villages 50 to 100 years ago, and the death-rate is as high as would be expected.

---

[1] Proceedings of the Royal Society of Medicine, 1914, vol. vii., No. 4, Surgical Section, p. 137. THE LANCET, Jan. 24th, 1914, p. 243.

he new course on sanitary science in the tropics enerally should be of great value, and further articulars may be had from the secretary, eamen's Hospital, Greenwich, London, S.E.

TUBERCULOSIS IN THE NECROPSIES OF CHILDREN.

THE Local Government Board has now issued he special reports on this subject[1] to which allusion as made in the annual report of the medical fficer of the Board for 1912–13, which we recently eviewed.[2] The first, by Dr. A. Eastwood and Dr. . Griffith, relates to 150 post-mortem examinations f children dying in various London hospitals (not pecially devoted to the care of tuberculous atients), while the second, by Dr. A. S. Griffith, eals with somewhat similar observations at Cam-ridge on a consecutive series of 45 children. These eports illustrate the great extent to which tuber-ulosis is a cause of death in town children, and e frequency with which this disease may be esent in children who die from other causes. aking the first of these reports, it appears that of e 150 post-mortem cases in children between the ges of 2 and 10 death was due to tuberculosis in , and evidence of tuberculosis was found in others. This series of 33 comprised 16 showing sions of tuberculosis in which the bacilli were pparently dead, and 5 in which, though there ere no tuberculous lesions in any part of e body, tubercle bacilli were obtained, by inocu-tion and culture, from the cervical, bronchial, mesenteric glands. Taking the 94 cases in hich evidence of tuberculosis was found, the atomical appearances indicated that in 22 the ands draining the alimentary tract had been imarily invaded, in 52 the respiratory tract emed to have been the seat of invasion, and in the anatomical evidence as to the portal of try was inconclusive. As all three investigators ought to this work special knowledge acquired their researches for the Royal Commission on uman and Animal Tuberculosis, their investiga-ns into the type of bacilli met with in these ses has exceptional value. In the 94 cases above ferred to the bovine type predominated in those which on anatomical grounds infection was nsidered to have taken place by the alimentary act; on the other hand, bacilli of the bovine pe were found in 1 only out of the 52 cases parently due to respiratory infection. The cteriological distinctions between bovine and man types were as a rule quite definite, ough in one instance a strain was found which uld not be classified as either "human" or ovine" on the accepted standards. In the second port, which gives broadly similar results, Dr. S. Griffith lays stress upon the consideration at absence of bacilli of the bovine type from ses in which the primary lesions were thoracic obably signifies that when the lungs of children affected by tuberculosis of "human" origin infection has been acquired through the spiratory passages and not through entry by y of the alimentary tract. While there is idence that tubercle bacilli, which reach the mentary canal as a result of swallowing ected dust or other material, may pass rough the mucous membrane of the alimentary tract without leaving trace of their passage, it is unlikely that an anatomically primary thoracic tuberculosis would be caused, for if this were common anatomically primary tuberculosis of the lungs should be frequently met with as a result of swallowing bovine bacilli. Many other matters of interest are dealt with in these reports, and it would be of obvious value if similar researches could be extended—for example, as to the differences in the relative prevalence of human and bovine infection in different localities.

THE VALUE OF THE SPLEEN RATE IN MALARIOUS DISTRICTS.

IT is obviously of the first importance that sanitary administrators and other responsible officials in malarious regions should be able to appraise the amount and intensity of the infection in any district, and also that they should be able to watch and make definite record of the changes or fluctuations which may occur in the incidence of the disease after the adoption of antimalarial measures of one or another kind. Various methods have been put forward from time to time for gauging the extent to which malaria may exist in a locality, but most of them have been open to objection of some sort, either, for example, on the score of difficulty of application or because of the excessive amount of time or trouble required to carry them out. The test which is now most generally accepted, and which is at present largely used by experts for the purpose, is that known as the "spleen rate"—that is, the proportion of all children in the place showing evidence of any enlargement of the spleen. It is, however, admitted that diseases other than malaria may give rise to enlarged spleens, kala-azar for instance; but it is believed that with care it is possible in most localities to guard against mistakes from this source. The simple spleen rate, though fairly free from observational error, is not altogether exempt from it, and this has been found to arise more particularly in connexion with the difficulty of deciding whether a spleen which is "just palpable" under the ribs is, or is not, a pathological enlargement, especially where young children are concerned. When reporting upon his inquiry, made last year, into malaria in Cyprus, Sir Ronald Ross drew attention to this difficulty and expressed his intention, with the view of removing doubt, of making further study of the spleen in a number of children in some non-malarious country like England. With the assistance of two expert officers of the Indian Medical Service, Major S. R. Christophers and Major E. L. Perry, Sir Ronald Ross has now carried out his intention and has made detailed and careful examination of the spleens of nearly 500 children attending five large schools in the north of London. Many of the cases were examined by all three observers, and seldom by less than two of them, and the results have been published in the *Indian Journal of Medical Research* (Vol. I., No. 3). Various methods of palpation were [illegible]

[illegible] 5 cases could the spleen be said to be palpable, and this gives a spleen rate of only 1 per cent.; in 5 other instances doubt arose as to whether the spleen could be felt or not. Including these doubtful cases, the spleen rate is only 2 per cent., whereas in some 20 or more [illegible] by Sir Ronald Ross in [illegible]

blin; [illegible] ice 2s. 3d.

became reddened, and in January one of them broke down, giving rise to a fistula discharging sanious pus. One of the remaining tumours, the largest of which had attained the size of a walnut, was punctured, and the thick pus which was thus secured was utilised for cultures. Treatment with potassium iodide by the mouth was successful in leading to a rapid absorption of the tumours, leaving no trace apart from a scar in the site of the fistula, which had dried up as the swellings disappeared. The second case was that of a young soldier who developed two swellings similar in character to those observed in the other patient. One of these was incised, and the dirty yellow pus which was found was used for cultivation. Various media were tried, but the results were negative except in bouillon with or without gelatin. Even on these media growth was slow; the colonies, which were rounded, enlarged slowly, and changed from a rose tint to a deeper and deeper shade of brown. Examination of these colonies showed that they consisted of mycelial threads, straight or slightly curved and divided by transverse lines into segments which sometimes became completely separated from the main mass and themselves formed the origin of new masses. For these and other reasons the writers regard the fungus as quite distinct from that of sporotrichosis; the name which they propose for it is Chalara pyogenes, and for the disease which it appears to cause in man the term "chalarosis" is suggested. It should be added that experimental inoculation of the cultures into the subcutaneous tissues of animals provoked the formation of lesions very similar to those observed in the human subject.

Dr. Paul Ferreyrolles will give a demonstration before the Fellows of the Royal Society of Medicine on Wednesday, April 8th, at 5 P.M., on Colloidal Metals by the kinematograph, and of his experimental work showing the production of immunity by means of the hypodermic use of colloidal metals. Mr. Henry Crookes will at the same meeting give a demonstration by the ultra-microscope of various colloidal metals in solution. Very little is known in this country of the work that is being done in this connexion in France, and these demonstrations should be of great interest to the medical profession.

THE King has granted to Dr. Morden Carthew, first assistant medical officer to the local sanitary department at Bangkok, licence and authority to wear the Insignia of the Third Class of the Order of the Crown of Siam, which has been conferred upon him by His Majesty the King of Siam.

Dr. Carl H. Browning, director of the Laboratory of Clinical Pathology at the Western Infirmary, Glasgow, has been elected director of the Institute of Pathology at the Middlesex Hospital, recently erected through the munificence of Sir John Bland-Sutton.

Mr. Raymond Johnson, surgeon to University College Hospital, London, has signified his intention of being a candidate at the forthcoming election to the Council of the Royal College of Surgeons of England.

Dr. Barty King has been elected a Corresponding Member of the International Congress of the Antituberculosis Association, Berlin.

SURGEON-GENERAL GORGAS AND THE PANAMA CANAL.

THE COMPLIMENTARY DINNER TO SURGEON-GENERAL GORGAS.

A DINNER was given on Monday evening last at the Savoy Hotel by the medical profession to Surgeon-General W. C. Gorgas, the principal sanitary officer of the Panama Canal Commission, who has recently been appointed Surgeon-General-in-Chief to the United States Army. Sir Thomas Barlow, President of the Royal College of Physicians of London, presided over a distinguished company, which included:—

The Archbishop of Canterbury, the Lord Chancellor, the American Ambassador, Dr. S. T. Darling (chief of the Research Laboratory of the Panama Canal Commission), Major R. E. Noble (General Inspector of the Sanitary Department of the Panama Canal Commission), Viscount Bryce, Lord Moulton of Bank, Sir Rickman J. Godlee (President of the Royal College of Surgeons of England), Sir Francis Champneys (President of the Royal S[illegible] rrier (President of the Medical Socie[illegible] the British Medical Association), Sir [illegible] o Society of Tropical Medicine and Hygiene), Sir William Osler, Surgeon General A. W. May (Director-Ger[illegible] Surgeon-General Sir L. Gubbins ([illegible] Service), Sir Ronald Ross [illegible] Griffith (the American [illegible] fessor Howard Marsh, S[illegible] Ramsey Macdonald, M[illegible] Cheyne, Sir John Twee[illegible] fessor Simpson, Sir J. Rose Bradford, Sir Frederic Eve, Fleet-Surgeon P. W. Bassett-Smith, Sir A. A. Bowlby, Sir Lionel Spencer, I.M.S., Sir J. Goodhart, Sir Alfred Keogh, Sir Arbuthnot Lane, Sir J. Porter, Sir Shirley Murphy, Sir Anderson Critchett, Dr. Newsholme (Principal Medical Officer to the Local Government Board), Sir G. Newman, Sir J. Barr, Surgeon-General W. G. Macpherson, Mr. G. H. Makins, Dr. S. Monckton Copeman, Mr. James Cantlie, Dr. John Eyre, Dr. A. J. Carter, Surgeon-Lieutenant-Colonel P. J. Freyer, Dr. Arthur Latham, Sir StClair Thomson, Major S. L. Cummins, R.A.M.C., Dr. T. B. Hyslop, Dr. H. A. Latimer, Mr. P. P. Laidlaw, Dr. H. H. Dale, Dr. Guthrie Caley, Dr. R. A. Gibbons, Mr. J. B. Lawford, Dr. H. A. Alford Nicholls, Dr. Harvey Hilliard, Mr. J. H. Dauber, Dr. F. Parkes Weber, Dr. T. M. Legge, Dr. E. F. Bashford, Dr. David Thomson, Dr. J. G. Thomson, Dr. C. F. Harford, Mr. Herbert S. Pendlebury, Dr. Seymour J. Sharkey, Dr. W. Hale White, Colonel W. G. King, Lieutenant-Colonel O. L. Robinson, R.A.M.C., Major J. A. Masters, Mr. E. Alan Masters, Professor Wm. Russell, Major S. P. James, I.M.S., Dr. Edwin Rayner, Dr. G. C. Low, Colonel B. M. Skinner, A.M.S., Dr. A. K. Chalmers, Dr. Samuel West, Dr. William Hunter, Dr. P. S. Abraham, Dr. A. J. Hall, Dr. H. F. Heath, Dr. W. H. Hamer, Dr. H. H. Tooth, Dr. H. Scurfield, Dr. A. W. C. Cameron, [illegible] Havilland Hall, Colonel A. Alcock, [illegible] Hayward Pinch, I.M.S., Dr. Daws[illegible] Mr. Stanley Boyd, Dr. S. G. Mo[illegible] y E. M. Wood, Dr. E. Farquhar Buzzard, Dr. W. S. A. Griffith, Dr. S. Squire Sprigge, Dr. E. S. Pasmore, Dr. Hector Mackenzie, Mr. H. G. Plimmer, Dr. Purves Stewart, Dr. W. T. Prout, Dr. T. D. Acland, Dr. G. Newton Pitt, Mr. C. B. Lockwood, Dr. Archibald Garrod, Mr. Arthur E. Barker, Mr. L. Reyersbach (Ex-President, Transvaal Chamber of Mines), Dr. F. J. Smith, Mr. T. Jenner Verrall, Mr. Deane Butcher, Mr. C. J. S. Thompson, Dr. G. William Hill, Mr. J. Y. W. MacAlister, Dr. J. Mitchell Bruce, Mr. C. A. Ballance, Mr. James Berry, Dr. H. Lyon Smith, Dr. D. E. Anderson, Dr. H. Andrew Foy, Dr. Louis W. Sambon, Mr. Percy Dunn, and Mr. Robert Donald.

The Royal toasts having been briefly proposed by the Chairman, Lord BRYCE proposed the toast of "The President of the United States," and in the course of his speech alluded to the work of the International Health Commission of the United States, whose director, Mr. Wickliffe Rose, had recently been in personal conference with the British Colonial Office, with the result that the two great Anglo-Saxon races will coöperate to fight disease, ankylostomiasis being the immediate objective of the campaign.

The AMERICAN AMBASSADOR, in responding, said that the President of the United States was a man of scientific training, who had brought his knowledge of history and theoretical government to the service of his country with most fortunate results, and he instanced the appointment of Surgeon-General Gorgas to the directorship of the Medical Department of the United States Army as a proof of scientific methods of administration.

The CHAIRMAN briefly stated that the idea of a dinner of welcome to Surgeon-General Gorgas during his visit to England had originated with Sir William Osler, and had been at once supported by Sir Havelock Charles, President of the Society of Tropical Medicine, by Professor W. J. R. Simpson, for the London School of Tropical Medicine, and by the Royal Society of Medicine, the British Medical Association, and the Royal Colleges, and that with the view of making the occasion representative the presence had been desired of certain great men of the realm in Church and State.

Sir HAVELOCK CHARLES than proposed the health of Surgeon-General Gorgas in forcible and eloquent terms. He pointed out that the distinguished guest of the company had proved that tropical scourges could be controlled, and said that Surgeon-General Gorgas, having been given a free hand, and having made full use of the knowledge placed at his disposal by the discoveries of Manson and Ross, had controlled them in the Isthmus. Thus he had enabled his country to succeed where the brilliant French engineers had failed, for he had conquered the pestilence which had rendered the work of the French abortive.

Surgeon-General GORGAS responded with great grace and modesty. He began by alluding to the fact that 45,000 of the 60,000 labourers on the Canal were coloured subjects of the British Empire, hailing from the West India Islands. Excellent subjects of the British Crown, and members of the Church of England, they were inclined to claim the Canal, lock, stock, and barrel, and personally annexed most of the Bibles which had been presented for the use of the settlement. Their faith only faltered temporarily in the Empire to which they belonged, and that was when, without due notice, their form of payment had been changed to money orders representing a vast weekly sum, which the unprepared officials at the Barbados post-office could not cash on the spot. Confidence, said Surgeon-General Gorgas, was later restored. Referring to the progress of the Canal, he said that when he left in October the smaller boats employed in the works were passing through; it was believed that some commercial traffic would take place in July, and that the Canal would be formally opened next January. He concluded a speech, which was received throughout with signs of the obvious pleasure of the audience, by acknowledging the kindness and courtesy extended to himself and his colleagues, Major Noble and Dr. Darling, during their visit, closing with a simple and sympathetic [illegible] called up in the breast of [illegible] y the sight of Westminster [illegible] and by walking in the streets where Dickens's and Thackeray's heroes had walked.

Sir THOMAS BARLOW briefly responded to the toast of "The Chairman," which was given by Sir WILLIAM OSLER.

SANITARY WORK AT PANAMA.

Earlier in the day Surgeon-General Gorgas gave an address before a crowded audience in the Robert Barnes Hall of the Royal Society of Medicine on the measures adopted in combating malaria and yellow fever in the Isthmus of Panama. The chair was occupied by Sir FRANCIS CHAMPNEYS, the President of the society.

The PRESIDENT, in briefly introducing the lecturer, extended to him, in the name of the society, a warm welcome for two reasons: firstly, because his work was an object lesson to the world and especially to our own country, which was so slow to encourage science. It would enable us to understand how an intimate acquaintance with the life-history of a gnat could change the map of the world. And the second count in the welcome was the fact that in a line of research in which our own countrymen had laboured so successfully this grand piece of work had been accomplished by one of our American cousins.

Surgeon-General GORGAS first dealt with the geography of the zone under consideration, explaining that the Canal was 50 miles long and ran almost due north and south.[1] The United States leased a strip of land on each side of the Canal, whose area, therefore, was about 500 square miles, two-thirds of which was rough, broken, and mountainous, the remaining one-third low and swampy. The bad health reputation of the Isthmus was chiefly due to the fact that during the last 400 years a large number of unacclimatised persons had always been present there. The climate was not very disagreeable, for while it was warm all the year round, its temperature was not so high as that of many United States localities during the summer, and its rainfall was also exceeded in other places. The perpetual moist warmth constituted ideal breeding conditions for mosquitoes. Before going to Panama he had done four years' sanitary work at Havana. It was known that the introduction of large numbers of workers into Panama would mean the outbreak of yellow fever, for there had been cases of it in 1904, in which year the Americans started their work, the French having commenced in 1880. But for the advances in tropical medicine in the meantime, probably the later army of workers would have been as much harassed by disease as were the French; and it was a matter of pride to him that the discoveries connected with the insect transmission of malaria and yellow fever were made by men of the Anglo-Saxon race. Health officers were appointed for Panama and Colon. Panama City was divided into six inspection districts, and an inspector was appointed to the charge of each. An ordinance required that every unacclimatised person should each day report himself to the sanitary inspector. It was found better and more economical to employ additional men to hunt up the people than to have an elaborate scheme of fines and punishments for failure to report. This was not very difficult, because the native was immune to yellow fever; the victim was the recently arrived white man. These persons the inspector soon got to know, and could keep in touch with them. If a non-immune person was found to be sick, he was reported to the health officer; and if the case proved to be yellow fever, he was given the option of either going to hospital or having home treatment. If the latter, a skilled member of the sanitary force screened the room or rooms selected, and the only entrance and exit was guarded by an officer to see that no unauthorised person entered. No attention was paid to the patient's clothing, because it was found that clothing could not infect the mosquito, and it would be safe to release the patient from quarantine on the third day except for the possibility of some mosquitoes having got into the screened room and become infected. Nor was it necessary, in the event of death from yellow fever, to give special attention to the cadaver, because it could not infect the mosquito. But the building, when the patient left, or died there, was carefully pasted up and fumigated. The mosquitoes were not dangerous until the tenth or twelfth day after biting. The stegomyia was a poor flier, and it spent about a week in the larval stage, during which it had to live in water. Thus it was necessary for each inspector to get round his district once a week. He had to take with him a sufficient force to attend to sanitary nuisances, such as water puddles, or tin cans, or old bottles wherein mosquitoes might breed. Ordinances were passed making it a sanitary nuisance for persons to have mosquito larvæ on their premises, and they carried with them the power for health officers to inflict punishment or fines for non-observance; but the offender was always released from the punishment when the nuisance was abated. Gentleness and persuasion were a great force with Latin-American populations, whereas police-court rigour, as we know it here, would probably result in much awkwardness in attempting to circumvent the officers. The country districts were divided into 25 sanitary districts, and they comprised 30 villages, varying in population from 8000 or 10,000 to a few hundreds. Probably the limit flight of the anopheles was 200 yards. The principal means of getting rid of the mosquitoes was by drainage; indeed, if officers resorted to other measures, that was looked upon as a confession of failure with the chief means, drainage. The principal form used was that common in farming, known as the surface drain. But owing to the rapid growth of grass in this region the ditches had to be cleared out every two or three weeks. A permanent drain [illegible] subsoil tiles. Sunlight and wind proved destructive of mosquito life, hence the insects sought the grass and the brushwood for shelter. Inspectors had to keep this growth cut short for a distance of 200 yards round all villages and suburban residences. He was speaking largely of the antimalarial crusade, but the remarks applied also to yellow fever. It must be remembered in the case of the stegomyia that it was the female alone which bites, and generally at night; it then sought a dark corner in which to rest while digesting its meal of blood. For killing infected mosquitoes a test-tube was used, into the bottom of which was placed material moistened with chloroform; the insect readily fell stupefied into the tube, and was detained and sent uncrushed to be counted and classified at the central office. This was done daily. If a man caught only some of the mosquitoes each day, by

[1] THE LANCET, June 3rd, 1905, p. 1530; June 6th, 1908, p. 1646.

Hospital, now called the Hospital for Women and Children, for the past 13 years. She gave figures of the number of patients treated at the hospital in each year since 1893, and these showed a decrease from 736 patients in that year to 340 in 1912. This fall, she said, was partly due to a change in general conditions and partly to the fact that in the earlier years women came to the hospital from garrison towns. The figures were also very much influenced by the fact that in the earlier years patients were of a class who left the hospital directly they were free from symptoms; at the present time the patients remain in the hospital for longer periods and finish their treatment. During the present year the number of patients was much larger than had been the case in corresponding periods for a number of years. Miss Garrett thought this was probably the result of the greater publicity of the subject during the last few months. The name of the hospital was changed some years ago, and this had had good results in getting rid of prejudice against the hospital; in particular, cases now came to the hospital at an earlier stage of the disease. Most of the patients treated at the hospital were very young girls, the average age being 20, and there were very few professional prostitutes.

At the twenty-fourth meeting evidence was given by Dr. Amand Routh, consulting physician to the Charing Cross Hospital and to the Samaritan Free Hospital for Women and Children.

Dr. Routh said that from figures which he had obtained he had formed the conclusion that the infant mortality before the period of full birth was as high as in the first year of life, so that the total mortality during the intra-uterine life and the first year after birth was about one-fourth of the possible children. He thought that syphilis was the main cause of stillbirths, and also probably of a large proportion of early intra-uterine deaths, and he suggested various measures which might be adopted with the object of obtaining reliable statistics, of assisting diagnosis, and of facilitating the application of treatment. These measures included the extension of the compulsory registration of stillbirths to the whole country; arrangements under which poor women might receive medical supervision during pregnancy; the provision of the pre-maternity wards in every locality; the formation and endowment of research laboratories in all general and lying-in hospitals; and arrangements for financial assistance to poor pregnant women during the later months of pregnancy. Dr. Routh said he was not in favour of the compulsory notification of venereal diseases, for unless anonymity could be secured and be believed in many men and most women would not consult a doctor, but would either remain untreated or consult venereal quacks who would greatly multiply. He felt that voluntary notification would be entirely unreliable statistically. He advocated the establishment of venereal clinics in all districts, but thought it was important that they should not be known by any name of the nature of "venereal."

Birmingham Children's Hospital. — The annual meeting of this institution was held on Feb. 23rd. The report of the board of management showed that the number of patients treated during 1913 was: in-patients 914, compared with 845 in 1912; out-patients 13,897, against 12,295; and casualties 628, against 686. The average length of stay in hospital was 22·18 days, and the average cost per week for each inmate (staff and patients) was 4*s.* 7*d.*, as against 4*s.* 5*d.* in 1912. The new building is well in hand, and the opening ceremony is expected to take place in the summer of 1915. £9000 are still required to open the new hospital free of debt. During the year the committee has been impressed with the necessity of removing the out-patient department from Steelhouse-lane to the new site, as the present accommodation is very inadequate for the present work. The cost of a new out-patient department would be about £10,000, but against this there would be very considerable economies in annual expenditure. The accounts of ordinary income and expenditure show a deficiency of £235, as compared with £86 in the previous year, owing partly to an increase in expenditure and partly to a falling off in special items of revenue. During the year there were 151 deaths, giving a death-rate of 16·5 per cent., as compared with 15 per cent. the previous year.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Radnorshire County Council.—Medical inspection is in very primitive condition in Radnorshire. Dr. L. W. P reports that as he is not supplied with adequate assista about half his time is taken up with clerical work. Becau of this second visits to schools have been impossible, and reinspection or following-up work has been systematica carried out nor any sanitary survey of the schools ma Goitre prevails largely, but whereas in 1911 the percenta of cases among children inspected was 3·4, in 1912 it v 2·1 only. The total children inspected were 1314, a belonged to four age groups, those about 5, 7, 10, and years old respectively.

Salop County Council.—Dr. James Wheatley lays empha on the necessity for bringing the ordinary child up to highest pitch of physical fitness possible by remov unphysiological modes of living. The preventive w should consist of improvement of school premises, provis of proper playgrounds, efficient physical exercises, hygie instruction of children, and coöperation with the sanit authority to prevent damage to health before school a The school medical officer's report is sent to the h teachers of each school and has in consequence been v widely read. This useful practice might well be imita elsewhere. The total number of children examined in year was 13,227, of whom 3750 were reinspections and were "specials." With reference to defective vision att tion is called to the defective type of school Bibles adoption of the British Association standards for the t of all new books is recommended and the prevention needlework or any work involving eye-strain under ei years.

East Sussex County Council.—Mr. A. G. R. Foulerto report includes, and gives special prominence to, spe studies by Dr. Arthur Beeley on pulmonary tubercul among school children in the county, and by Mr. George Fi on the local distribution of cases of tonsils and adenoi The total children examined since medical inspection beg have been taken as the basis of the tuberculosis repo These children are 47,168 in number, and among these cases of pulmonary tuberculosis have been found. Owing some cases being second examinations these figures can be used to give a percentage, but in 24,128 which available the percentage is 0·04. The phthisis dea rate per 1000 in 1910 for all ages in England Wales was 1·08, in East Sussex 0·8. The low centage of school children affected is ascribed par to the absence of large towns and partly to onl small proportion of the population being engaged in healthy trades. But the chief factor is probably the met of diagnosis. Mere harshness of breath sounds and longation of expiration have not been accepted as evidenc tuberculosis by themselves, nor have catarrhal signs. M cases of tonsils and adenoids occur in rural areas than urban. The distinctly urban districts of Seaford, Newhav and Portslade-by-Sea give percentages of occurrence cases of enlarged tonsils and adenoids 3·6, 2·8, and 2 the urban districts which have predominantly "rur characteristics of Haywards Heath and Burgess Hill g percentages of 3·72 and 3·6 respectively. The sch medical officer suggests dampness as a cause; the probabi would seem to be that dirty and carious teeth are commo in the relatively backward country districts and that enlar adenoids and tonsils depend frequently upon chro infection from the mouth.

Devonshire County Council.—Among 17,967 children e mined only 0 05 per cent. were found to have tuberculo Lantern lectures on tuberculosis are given in different distri by the medical officers. No reappearance of cerebro-spi meningitis is recorded, and this is ascribed to the season proving unfavourable to the transmission of the vi The various defects noted are given in tables classi according to sex, district, and age, with a paragraph explanatory comment beneath. The method is simple effective and makes the report easy of reference. curative treatment is carried out except in a few cases individual effort. Less than 40 per cent. of defects need medy have been treated. The backward condition of following-up" and hygienic work may be inferred when we ote that Brixham is marked out for distinction as having omething over 100 children who now clean their teeth under the stimulus of a tooth-brush club) as against no hildren formerly.

Durham County Council.—The report of Dr. Eustace Hill ncorporates individual reports by three of the assistant nedical officers and by the school nurse, who also acts as 'health visitor." In this the social conditions aspect of nedical inspection is brought prominently forward. A ounty ophthalmologist, Dr. A. T Paterson, is employed in reating disease of the eyes and defective vision.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose at the middle of this year is estimated is, 8598 births and 5286 deaths were he week ended Saturday, March 21st. The annual rate of mortality in these towns, which had been 15 1, 15 8, and 15 4 per 1000 in the three preceding weeks, further declined to 15·2 per 1000 in the week under notice During the 11 weeks of the current quarter the mean annual death-rate in these towns averaged 16 4, against 16 1 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5 3 in East Ham, 6 6 in Edmonton, 6 7 in Oxford, 6 9 in Swindon,

h, 24 1 in

than the

hich were

numbers

rising from 397 to 441 in the four preceding weeks. Of these 444 deaths, 155 resulted from whooping-cough, 107 from measles, 73 from infantile diarrhœal diseases, 51 from diphtheria, 37 from scarlet fever, and 21 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1 2 and 1 3 per 1000 in the two preceding weeks. The deaths attributed to whooping cough, which had steadily increased from 110 to 143 in the four preceding weeks, further rose to 155 last week, and caused the highest annual death-rates of 1·3 in Gateshead and in Swansea, 1·4 in Plymouth and in South Shields, 1·7 in Exeter, 1 8 in Darlington, 2 0 in Dudley, 2 1 in Sheffield, and 2 7 in Great Yarmouth. The deaths referred to measles, which had been 101, 118, and 113 in the three preceding weeks, further declined to 107 last week; the highest death rates from this disease were 1·1 in Bradford, in Sheffield, and in Cardiff, 1·8 in Nottingham and in Stockton on Tees, 1·9 in Burnley and in Barnsley, 2 0 in Dudley, and 3 0 in Swansea The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 83, 59, and 74 in the three preceding weeks, were 73 last week, of this number 17 were registered in London, 6 in Liverpool, 6 in Manchester, 3 in Burnley, and 3 in Leeds. The deaths attributed to diphtheria, which had been 72, 60, and 67 in the three preceding weeks, fell to 51 last week, and included 16 in London and 3 in Liverpool. The deaths referred to scarlet fever, which had been 34, 34, and 31 in the three preceding weeks, rose to 37 last week, of which 8 occurred in London, 4 in Liverpool, and 3 in Birmingham. The fatal cases of enteric fever, which had been 8, 20, and 13 in the three preceding weeks, rose to 21 last week, and included 4 in London, 3 in Manchester, and 2 in Sheffield.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily decreased from 3599 to 3222 in the seven preceding weeks, had further declined to 3173 on Saturday last; 319 new cases were admitted during the week, against 401, 340, and 320 in the three preceding weeks These hospitals also contained on Saturday last 1295 cases of diphtheria, 338 of whooping cough, 129 of measles, 79 of enteric fever, and 1 of small-pox. The 1228 deaths from all causes in London were 10 fewer than the number in the previous week, and corresponded to an annual death-rate of 14 2 per 1000. The deaths referred to diseases of the respiratory system, which had been 243, 260, and 223 in the three preceding weeks, rose to 250 in the week under notice, but were 153 below the number in the corresponding week of last year.

Of the 5286 deaths from all causes in the 97 towns, 185 were attributed to different forms of violence, and 388 were the subject of coroners' inquests. The causes of 37, or 0 7 Bradford, Hull, Newcastle on Tyne, and in 56 other smaller towns. Of the 37 uncertified causes of death, 6 were registered in Birmingham, 6 in Liverpool, 3 in St Helens, and 2 each in Warrington, Rochdale, Sunderland, South Shields, and Gateshead.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 636 births and 463 deaths were registered during the week ended Saturday, March 14th. The annual rate of mortality in these towns, which had been 19 1, 20 8, and 19 2 per 1000 in the three preceding weeks, rose to 20 0 per 1000 in the week under notice During the ten weeks of the current quarter the mean annual death rate in these Irish towns averaged 21 5 per 1000; in the 97 large English towns the corresponding rate did not exceed 16 6, while in the 16 Scotch towns it was equal to 18 5 per 1000 T

Lieutenant-Colonel F. J. Morgan has arrived home from India. Lieutenant-Colonel M. P. C. Holt, D.S.O., has been appointed to the Aldershot Command. Lieutenant-Colonel T. B. Winter has been appointed to the charge of the Military Hospital at Canterbury. Lieutenant-Colonel J. Kearney has been appointed to the medical charge at Landguard Fort. Lieutenant-Colonel J. F. Donegan has embarked for a tour of service in India. Lieutenant-Colonel C. C. Reilly has been selected as Senior Medical Officer at the Military Hospital, Calcutta. Lieutenant-Colonel A. Kennedy has been placed under orders for service abroad during the trooping season.

Major H. W. Grattan has been selected for appointment as Honorary Surgeon to the Viceroy and Governor-General of the East Indies. Major E. W. Bliss has been appointed to the Eastern Command for a tour of duty. Major H. P. W. Barrow has been appointed for temporary duty at the Medical Division of the War Office. Major M. H. Babington has taken up duty in the London District. Major F. Harvey has been appointed to the Military Hospital at Colaba. Major H. W. Long has joined at Upavon. Major P. S. O'Reilly has been appointed to the Medical Staff of the Royal Arsenal at Woolwich. Major A. M. Maclaughlin has been appointed to hold charge of the Military Hospital, Bellary Cantonment. Major L. M. Purser has joined at Meerut Cantonment. Major R. L. Argles has been appointed to the Military Hospital at Ferozepore. Major J. T. Johnston has been transferred from Bareilly to Lucknow Cantonment. Major F. S. Penny has been appointed to the Irish Command.

Captain T. S. Dudding has been transferred from the Bombay Brigade to Belgaum Cantonment, for duty at the Military Hospital. Captain P. S. Stewart has been appointed to the Southern Command for duty. Captain W. K. Beaman has arrived home from the Military Hospital at Malta, tour expired. Captain A. G. Jones has been selected for appointment as Officiating Staff Surgeon at Rawal Pindi Cantonment. Captain N. D. Walker has taken up duty at the Military Hospital, Quetta Cantonment. Captain A. C. Amy has joined at Agra. Captain N. Low has taken up duty as Specialist Sanitary Officer at the Military Hospital, Colchester. Captain J. A. Bennett has been appointed to the Dublin District for duty. Captain W. F. H. Vaughan has arrived home on leave of absence from Malta. Captain F. C. Lambert has been selected for appointment as Specialist in Advanced Operative Surgery to the Lucknow Division. Captain H. T. Stack has joined at Ranikhet. Captain E. B. Lathbury has been appointed to the Cork District for duty. Captain T. C. Lucas has arrived home on general leave of absence from the Military Hospital at Bombay. Captain A. L. Stevenson has been transferred from Nowshera Cantonment to Secunderabad. Captain G. F. Dawson has arrived home on general leave of absence from Chakrata Cantonment. Captain J. H. Douglass has embarked for a tour of service in the Sierra Leone Protectorate.

Lieutenant T. E. Osmond has been appointed to the Military Hospital at Lucknow. Lieutenant L. Buckley has taken up duty at Rawal Pindi. Lieutenant W. McNaughtan has been transferred from Devizes to Netley. Lieutenant R. T. Vivian has been appointed to the Military Hospital at Bangalore. Lieutenant E. B. Allnutt has taken up duty at the Military Hospital, Poona. Lieutenant E. G. H. Cowen has been detailed for a course of Indian sanitation and hygiene at the Military Hospital, Lucknow. Lieutenant F. R. B. Skrimshire and Lieutenant D. W. Bruce have embarked for a tour of service in India.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels (dated Jan. 29th, 1914): John Fisher, D.S.O., Stanley Arthur Harriss, David Waters Sutherland, William Selby, D.S.O., V.H.S., Vivian Boase Bennett, and Charles Ross Pearce. Captains to be Majors (dated Jan. 29th, 1914): Samuel Herbert Lee Abbott, Alexander William Greig, Richard James Bradley, James Woods, Thomas William Harley, John William McCoy, Roger Durrant Willcocks, Thomas George Ferguson Paterson, Dewan Ganpat Rai, Robert Macpherson Barron, William Reith John Scroggie, and Herbert Henry George Knapp. Lieutenants to be Captains (dated Jan. 28th, 1914): Alister Ralph Speirs Alexander, Frederick William Hay, George Tate, Sidney Milverton Hepworth, and Jyoti Lal Sen.

Colonel R. W. S. Lyons has been appointed Surgeon-General with the Government of Bombay.

Lieutenant-Colonel and Brevet-Colonel B. G. Seton, Deputy Director-General, has been granted nine months' furlough home from India. Lieutenant-Colonel F. J. Dewes has joined at Myingyan. Lieutenant-Colonel C. A. Johnston has been appointed Senior Medical Officer at Bangalore Cantonment.

Major L. T. R. Hutchinson and Major F. S. C. Thompson have arrived home on general leave of absence from India. The services of Major W. D. A. Keys have been placed permanently at the disposal of the Government of Bombay. Major W. H. Cox has been granted six months' extension of leave home from India. Major N. E. H. Scott has been appointed Consular Surgeon at Mohammerah and Agency Surgeon (Second Class). Major E. E. Waters has been appointed Civil Surgeon, Calcutta. Major A. W. F. King has taken over charge of the Special Prison at Aden. Major G. Macpherson has been granted three months' privilege leave of absence. Major J. E. Clements has been confirmed in the appointment of Superintendent of Central Prisons.

Captain A. C. Munro has arrived home from India. The services of Captain A. F. Hamilton have been placed permanently at the disposal of the Government of Bombay. Captain A. Barnardo, on return from furlough, has been appointed Civil Surgeon at Comilla. Captain D. C. V. Fitzgerald has taken over charge of the Central Prison at Hyderabad, vice Captain W. A. Mearns. Captain L. Cook has been selected for appointment as Civil Surgeon at Sambalpur. Captain B. B. Paymaster has taken up duty at Karwar as Civil Surgeon. Captain H. H. G. Knapp has been appointed Superintendent of the Central Jail at Rangoon. Captain A. T. Pridham has been appointed to the charge of the Central Jail at Mandalay.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

John Gray Ronaldson to be Lieutenant (on probation) (dated Feb. 23rd, 1914).

Lieutenant Charles W. C. Myles resigns his commission (dated Jan. 7th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd South-Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: Captain John R. Benson to be Major (dated March 15th, 1914).

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Major Fred D. Woolley resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated March 21st, 1914).

2nd Welsh Field Ambulance, Royal Army Medical Corps: Charles William Chester Myles (late Lieutenant, Royal Army Medical Corps, Special Reserve) to be Lieutenant (to be supernumerary) (dated March 25th, 1914). Ivor Jones Davies to be Lieutenant (to be supernumerary) (dated Feb. 16th, 1914).

3rd Northern General Hospital, Royal Army Medical Corps: Major Arthur M. Connell to be Lieutenant-Colonel (dated Feb. 20th, 1914).

Wessex Clearing Hospital, Royal Army Medical Corps: Captain Clarence Isidore Ellis, from the List of Officers attached to Units other than Medical Units, to be Major (dated March 25th, 1914).

Attached to Units other than Medical Units.—To be Captains: Lieutenant Cuthbert D. S. Agassiz (dated Oct. 30th, 1913), Lieutenant Francis D. Blandy (dated Nov. 3rd, 1913), and Lieutentant Edward O. Libbey (dated Feb. 16th, 1914). Major William B. Fergusson resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated March 21st, 1914).

SURGEON-GENERAL GORGAS.

Surgeon-General W. C. Gorgas, of the United States Army, who is being honoured by the medical profession in this country during his visit to England, was on March 18th entertained at dinner by the Director-General of the Army Medical Service and the officers of the Royal Army Medical Corps in their mess at the Royal Army Medical College, Grosvenor-road. Dr. Darling, and Major Noble were also guests, and among those present were Surgeon-General May (Director-General of the Royal Naval Medical Service), Sir William Osler, Sir Ronald Ross, Professor Martin (Lister Institute), Professor Nuttall (Cambridge), and Surgeon-General Evatt.

DEATHS IN THE SERVICES.

Surgeon-General Sir Arthur M. Branfoot, K.C.I.E., I.M.S. (retired), at Folkestone on March 17th. He entered the Indian Medical Service in 1872, became Lieutenant-Colonel in 1895, and retired in 1903. Shortly after entering the service he was appointed civil surgeon at Cocanada, and later was resident surgeon at the General Hospital, Madras, and professor of hygiene at the Madras Medical College. Being greatly interested in the medical treatment of women he was appointed superintendent of the Government Maternity Hospital, and in 1881 became professor of midwifery there. In 1898 he saw service in Burma, where he was principal medical officer of the Rangoon District. In 1901 he was appointed surgeon-general to the Government of Madras, and later served as principal medical officer of the Bangalore and Southern Districts. Surgeon-General Sir Arthur Branfoot was President of the Medical Board at the India Office and a member of the Advisory Board for Army and Medical Services from 1904 till 1913.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 776.)

XL.—LONDON: MAINLY NON-PANEL VIEWS.

THE survival under the Insurance Act of some of abuses which prevailed under the old forms of b practice is a matter that naturally gives rise much anxious discussion. Some insured persons nplain that they are paying twice as much as merly for treatment and getting no better vice or attention than they did before the Act. here used to be club doctors who could anise for the very rapid treatment of numerous ients, and they sometimes made incomes ounting to as much as £1000 a year from scribers of 4*s.* annually, and managed to ieve considerable popularity at the same time. day, if these subscribers have become insured sons and remain faithful to their club doctor who ow on the panel, the latter may be giving the e sort of attendance to the same people, but is iving twice the pay. It is reasonably argued if the situation has to be found fault with, the t lies at the patient's own door, and that in se of time he will discover how to get better tment. But there is the other point of view— ely, that scrupulous practitioners may discover are giving themselves more trouble than necesand that it pays very much better in contract tice to imitate the methods of the former club ors. "The club doctors are teaching us to do ork easily and cheaply," has remarked to me than one practitioner who under the Act was obliged to do contract practice for the first It is the old difficulty of finding the *juste u*—the line between giving an insured person ame attendance as if he were a private patient, h on ordinary business principles may be ult, and repeating stock mixtures, which may y not be serviceable in the case, as in the old lays. Under the Act it is a prescription and a bottle that must now be given, and this elf constitutes an improvement, for the preion is a witness of the treatment adopted and fore increases the practitioner's sense of nsibility. In settling what is the *best* treatpossible to be given there can be no rule. the practitioner on his side does and what atient on the other side expects must differ more in some instances than in others; therea my journeys round I hear nothing but coms in one quarter, and perhaps in the next s many express themselves as highly satisfied.

sured Persons in Workhouse Infirmaries.

Vandsworth I saw a Poor-law doctor who very tically insisted that his parish was giving much medical aid as it did before the Act. he said, constantly sending to the workhouse ary insured persons who have fully paid up nce cards. Panel doctors, he complained, off their bad cases to the parish doctor." xcuse generally given is that the patient be properly attended in his home. The doctor, on his side, dares not refuse mendation to the workhouse for fear atient should die without treatment, and are now insured persons dying in the Poorrkhouse infirmaries. From Edinburgh and other towns similar complaints have been received. The number of permanent old paupers that used to be on the parish books has decreased, but this is a consequence of the Old Age Pensions Act and not of the Insurance Act. As for sanatorium benefit, it may, and indeed, I presume, will come in good time, but in the meanwhile many tuberculous cases in various parts of the country are being sent to the workhouse infirmary as formerly.

I have been asked whether these panel doctors who get rid of their troublesome cases by converting their patients into paupers are to receive the money paid by those other insured persons who do not employ any medical man on a panel, but subscribe for medical aid twice over that they may exercise their freedom of choice. Here at Wandsworth I have seen and talked to poor people, very poor people, who, though insured, pay a penny a week, preferring to consult one of the doctors of the Wandsworth Medical Aid Society, for example, rather than go to a panel doctor. But as a doctor of the Medical Aid Society remarked: "If I were to go on the panel, these poor people would come to me, because they are faithful to me. Am I right in compelling them to incur an extra expense they can ill afford? Perhaps I ought to go on the panel for their sakes." By not going on the panel he had, as a matter of fact, lost about a thousand patients, judging from his previous records of practice. Some of his old patients came and consulted him, though they were insured, and they paid shilling fees, but they were so miserably poor that he often had to remit the shilling. He preferred to attend such persons for a penny a week.

A good deal of hesitation exists in different London districts turning upon these points. While some doctors are wondering whether they had not better, after all, go on the panel, others have retired. One of these I hear left the panel after sending a circular to all the insured persons on his list explaining his motives for so doing. The difficulty has been more or less met sometimes by partners, one of whom goes on the panel and the other keeps off, thus striving to please all parties.

Absentee Panel Doctors.

From Wandsworth I went to Finsbury. Though this is a very different part of London in many respects, I found some analogous conditions, and, of course, others quite special to the district. One peculiarity of Finsbury is the great reduction of the population and the improvement in their conditions of life. Some 30 years ago there were 166,000 inhabitants, many of them crowded together in appalling slums. Now most of the slums have disappeared and there are only 86,130 inhabitants, of whom from 26,000 to 28,000 are insured persons. During the last 10 years the local improvements have been marked. The poorer section of the community have migrated to Walthamstow and more outlying districts, and if those who remain are still crowded according to modern estimates they are not so very poor. There is a large lodger class. The principal occupations are the butchering trade and general occupation in the meat market, though there are many printers and persons employed in the carrying trade. The latter are the worst paid section of the inhabitants, but there is comparatively little extreme poverty in Finsbury.

To attend to this population there are 24 medical practitioners residing in Finsbury, and in January, 1913, when the Insurance Act first came into force, only three of them went on the panel. But this does not mean very much, as the area is small and medical men from the surrounding districts attend to patients in Finsbury and are inscribed on the Finsbury panel. To-day of the medical men residing in Finsbury 11 are on the panel, as is also the medical officer of the Finsbury Dispensary. Only seven residents are not on the panel. Also there are not only many doctors on the Finsbury panel who do not live in the district, but some of them reside a very long way off. This constitutes so serious a grievance that its occurrence, if it became frequent, should be prevented, even if for this purpose further legislation is necessary. One of the Finsbury panel doctors, who has a list of about 2000 insured persons, lives at Clapton. A couple of partners who have a list between them of 3000 to 4000, live at Stoke Newington. Another firm of two doctors, who also have a long list of patients, live in Bloomsbury. This firm is much nearer, but even they live quite a mile away from their patients. Of course, the doctors on the panel have surgeries in the Finsbury areas, but what is to happen in a case of emergency and any night call? Many a patient in the Finsbury district lives too far from his panel doctor to be expected to go to fetch him.

Some scandals have arisen in connexion with this sort of thing, if the facts have been correctly reported to me. A doctor who lived some miles off, and who was on a panel at Hampstead, bespoke some rooms in the district where he intended to establish a surgery, but was never present to sign the red tickets of those who placed their names on his list. Of course, it is well known, and has been often stated in THE LANCET, that many doctors put their names promiscuously on various panels presumably on the offchance that something worth having might result. Then when they found but few insured persons elected to be on their list they gave the matter up. Though they did no work, never signed a red ticket or saw a patient, their names increased the length of the list of panel doctors, and the longer the list became the more those who were hesitating felt they had better hasten to join before it would be too late. Thus even broken promises were of use to the advocates of the Act, whose good features have been so obscured by these and similar blemishes.

Prosperity of Non-Panel Doctors.

As already stated, on a former occasion, the impression prevails that in an industrial district, where nearly all the practitioners are on the panel, there is an opening for one or two non-panel practitioners. But in Finsbury a larger number of practitioners have found it advantageous not to go on the panel. Calling on one of the most prominent of these non-panel practitioners, he told me that with the aid of a partner he used to attend to 1850 subscribers belonging to various clubs. But when the Insurance Act came into force these club patients were largely scattered among the panel doctors by becoming insured persons. During the first month after the Act came into force he consequently experienced a loss of £50. But the disadvantages of contract practice, as established by the Act, soon became apparent to the population of Finsbury, and the loss at first experienced was later turned into a profit. By the end of 1913 the receipts, as compared with the previous year, had augmented to the extent of £200 for the two partners. A neighbouring practitioner who earned in 1912 from clubs £400, and from private practice £300, in spite of the loss of all his clubs when the Act came into force, found that his receipts for 1913 have risen to £900, an increase o £200. Though I was not able to get the precis figures I am assured that the other Finsbury practitioners who have not gone on the panel are no suffering in any way.

This remarkable state of affairs is attributed t the fact that the list of insured persons whom th panel doctors of the district have undertaken t attend is far too long. They consequently canno examine the cases properly. A large proportion o the patients attended by non-panel doctors in th Finsbury district are insured persons. But th work of the non-panel doctor is much mor arduous than it used to be when he attended before the Act, to club patients. There are no for him very few trivial cases. When an insure person comes and pays a fee it is because he i really ill and does not feel that his panel docto has sufficiently studied the case.

Some examples of inefficient treatment by pan *practitioners, owing to haste and overwork, we* given to me with much detail. These, when substantiated, form very pungent criticisms of th Act in its present form, for one of the grea advantages claimed as resulting from the A was precisely the early detection and nipping in th bud of disease, together with the prevention o infection. But if panel doctors have not time t examine their patients properly the claim become of no account.

A great number of medical practitioners used t do club work as their contribution towards th relief of distress. They could not afford to hav many club patients if they treated them as carefully as private patients, but thought it was righ to give such treatment to labourers and othe who really could not be expected to pay fee Now, to-day, these doctors who did the club wor well and conscientiously have not hurried on the panel; on the contrary, it is the club doct who so arranged matters as actually to make a b profit out of the 1*d.* a week the club member pa who hurried on to the panel, and he saw in the A an opportunity of getting double pay for the sam amount of work. Thus it is that, at least i Finsbury, the public are beginning to draw a li of demarkation between the panel and the no panel practitioner, and this I hold to be disastro to the progress of medical science.

(To be continued.)

QUEEN VICTORIA'S INSTITUTE FOR NURSES.—The following members of the medical profession have be appointed by Queen Alexandra to the council of Que Victoria's Jubilee Institute for Nurses to hold office un 1917: Sir Dyce Duckworth, Surgeon-Lieutenant-Colonel S Warren Crooke-Lawless, Dr. A. H. F. Barbour, Dr. Arth Shadwell, and Mr. Charters J. Symonds.

A RADIUM FUND FOR PORTSMOUTH.—An appe for procuring a supply of radium for Portsmouth and distri made by the *Portsmouth Evening News* has met with generous response, the sum of £1000 having been contribut within a week. A conference has been held, under t presidency of the mayor, for the purpose of forming a tru to represent the subscribers, who will obtain the radium soon as possible and make arrangements for its safe custo at the Royal Portsmouth Hospital. According to the ter of the appeal the radium will be available for all classes sufferers in the district. The fund is still open, and it proposed that any balance not immediately required sh be invested by the trustees to form the nucleus of permanent fund for the purchase of radium or of any oth remedial agent for the treatment of cancer which medic science may discover.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LIVERPOOL.

Memorial to Sir Rubert Boyce.

THE late Sir Rubert Boyce was professor of pathology at the University of Liverpool, the first bacteriologist to the city of Liverpool, and also one of the founders of the Liverpool School of Tropical Medicine. To keep his memory green the entrance hall of the Thompson Yates laboratories of the University has been embellished by Mr. C. J. Allen, the well-known sculptor, with a beautiful mural tablet, having as a centre-piece a representation in marble of the deceased scientist's features, still familiar to the University and many in the city. The ceremony of unveiling the tablet was performed on March 20th, in the presence of a number of subscribers to the memorial, by the Vice-Chancellor of the University, Sir Alfred Dale. Prior to the ceremony the company assembled in the surgery theatre, under the presidency of Mr. J. W. Alsop, the Pro-Chancellor, when Sir Alfred Dale, in offering the memorial to the University on behalf of Mr. J. W. Hughes and others associated with him, spoke eloquently of Rubert Boyce. Where others already had their place it was right, he said, that Boyce should share the honour as he had shared the service and the struggle. What more natural home for his memorial could there be than the laboratories with which he would ever be associated? Boyce loved the University of Liverpool. Without him the University of Liverpool might have arisen, but would not have been what it was to-day. The monument spoke of one among his many ventures, in which he and his colleagues confronted, challenged, defied and defeated disease in alliance, as it seemed, with the forces of Nature in her most malignant moods. The battle was not over yet. The men who led the way—Alfred Jones and Rubert Boyce—had fallen before they reached the end. But in any great effort they owed most to the men who first believed that the effort was worth making, and that success, though distant, might still be won. The memorial had a pathos of its own. The form and face that they saw there were not those that they recalled in earlier years. Boyce had known disappointment, pain, weakness, the desolation of bereavement. Time had wasted and worn him; but he was still intrepid, still eager, adventurous, impatient as of old; broken in body but whole in spirit. That was the man they knew and admired and the friend they remembered with honour and affection. Mr. Alsop accepted on behalf of the University a memorial of one who was "a great man of the University and of Liverpool, a man of high ideals, intrepidity, perseverance, and deep sympathy." Professor Ernest E. Glynn, a co-worker for 12 years, bore testimony to the indomitable energy of Sir Rubert Boyce. He suggested that Boyce's many friends might like to subscribe to some memorial which would be more vital than a marble monument and which would tend to increase scientific knowledge, and offered, if there was any general feeling in the direction, to act as convener of a meeting of subscribers.

Dinner to Professor C. S. Sherrington.

The University Association entertained Professor Sherrington at a farewell dinner on March 14th at the New Midland Adelphi Hotel, on the occasion of his leaving Liverpool to take up his appointment to the Waynflete chair of physiology in the University of Oxford in succession to Professor Francis Gotch, who likewise went from Liverpool to Oxford.

Medical Magistrate.

The addition of the name of Dr. W. Macfie Campbell to the commission of the peace for the city has given great satisfaction to his professional brethren. Dr. Campbell is consulting surgeon to the David Lewis Northern Hospital, and has been president of the Liverpool Medical Institution and also of the Liverpool Athenæum.

Annual Service for the Northern Hospital.

The Lord Mayor and Lady Mayoress of Liverpool, along with members of the city council and representative members of the David Lewis Northern Hospital staff, attended Divine Service in St. Luke's Church, Liverpool, on Sunday last (March 22nd), when collections were made in aid of the institution. Shortly before 11 o'clock a procession was formed in Leece-street, and along a route lined with spectators the Lord Mayor and party walked to the church, where a large congregation was gathered. The sermon was preached by the Rev. Russell Darbyshire. The offertory realised £54 17*s.*

March 24th.

SCOTLAND.

West of Scotland Branch of the Incorporated Dental Society.

AN interesting exhibition of surgical and mechanical appliances for the use of dentists was opened last week in Glasgow. The exhibition, which was organised by the West of Scotland Branch of the Incorporated Dental Society, was held in conjunction with the annual meeting of the branch. At the meeting an address was delivered on the subject of Dental Politics, which dealt with the question of a National Dental Service. It was pointed out that in the near future dental insurance benefits would be offered in a comprehensive manner, and the question was how this could be so accomplished that students might be attracted to the dental schools. It was suggested that dentistry should be freed from the semi-medical course and from the control of the Medical Council.

Royal Hospital for Sick Children, Glasgow.

In view of the approaching completion and opening of the new Royal Hospital for Sick Children, Glasgow, the directors have made several appointments to take effect when a transference is made from the old hospital. Dr. T. Kennedy Dalziel with Mr. R. H. Parry, and Dr. R. Barclay Ness with Dr. J. B. McKenzie Anderson, who have long been respectively visiting surgeons and physicians, are to be consulting surgeons and physicians in the new hospital. Dr. Alfred A. Young and Dr. Alexander MacLennan, for many years connected with the out-door department, are to be visiting surgeons in the new hospital. Dr. Leonard Findlay, who has also a long connexion with the hospital, is to be visiting physician.

A Hospital for Orkney.

At a meeting of the trustees of the Balfour Hospital, Kirkwall, the clerk read a letter from Mrs. Garden, widow of the late Bailie Robert Garden, of

Kirkwall, in which she stated that her family wished to present to Orkney, in memory of her late husband and their father, a hospital of up-to-date design and adequate for the requirements of the county of Orkney, including the burgh of Kirkwall. Details as to site, building, and accommodation are under consideration, and the trustees will be advised as progress is made therewith.

Small-pox in Aberdeen.

Two further cases of small-pox are reported in Aberdeen—one that of a woman in a small shop in the same street as the family who first succumbed, and the other that of a young medical graduate studying for the Diploma in Public Health. With regard to the former it has now transpired that the mother of the family originally infected, who herself developed the rash after she, with other members of the family, had been removed to hospital, visited this shop and talked for some time with the owner one or two days before being removed to hospital. The second victim had, along with other members of the D.P.H. class, been given the opportunity of seeing the cases in the hospital; but only those who stated that they had been revaccinated were allowed to enter the ward, among those being the graduate who has developed small-pox. It is understood that on three separate occasions he had been revaccinated, but in no instance had it been successful, and the graduate considered himself immune. Both cases are slight.

Dundee and Phthisis.

Dundee public health committee has come to an arrangement with Arbroath to treat tuberculous patients from that burgh in Ashludie Sanatorium, rights over six beds being ceded to Arbroath, for which £15 per bed per annum of standing charges should be paid, and 30*s.* per week for maintenance charges while the beds were occupied. Arbroath also asked for attendance at Arbroath Dispensary by an assistant tuberculosis officer, and the committee agreed to appoint an assistant tuberculosis officer so that this might be done, Arbroath to pay £100 towards his salary.

Proposed Children's Hospital for Dundee.

At a recent meeting of the court of the governors of Dundee Infirmary it was intimated that the provision of a new children's hospital had been receiving the earnest consideration of the governors. Although hampered through lack of funds, the directors were prepared to open a second ward for children in the infirmary if financial support was forthcoming; they had the ward accommodation waiting to be occupied, and building accommodation was already started to accommodate more nurses, who would be necessary for this and other demands. It is thought by many that the accommodation for sick children in the General Infirmary is inadequate, and that a city of the magnitude of Dundee should have a special hospital for sick children; Dundee has an extremely high infant mortality. 3000 children were attended in the out-patient department of the infirmary during last year, and 45 beds in the infirmary and 35 in the sanatorium were occupied by children. But as a large proportion of them are suffering from tuberculous disease, in view of the possible extension of the Government scheme to children there is naturally hesitation as to inaugurating a large and costly scheme at the present juncture.

March 24th.

IRELAND.

Alleged Malingering.

THE Irish Medical Committee some months ago gave directions to the Local Medical Committees in the panel areas to make inquiries as to whether malingering under the National Insurance Act took place in such areas, and in particular to investigate specific complaints, if any were forthcoming, against particular medical men for laxity in certification. The local medical secretaries applied to the societies operating in their respective areas for information on the point, and the replies received have now been laid before the Irish Medical Committee. A few of the societies declined to give any help, but many others have replied fully. None venture to make any specific charges. The secretary of one of the largest societies in the North of Ireland has borne testimony to the very conscientious manner in which the profession of county Antrim has discharged the duty of certification, though he thinks that some medical men have confused incapacity of a patient to follow his ordinary occupation with incapacity to work. The Cork representative of a large English society also bears testimony to the thoroughly honest way in which certificates have been given by medical men in Cork. Many secretaries declare that they have not experienced any excessive claims for sickness benefit. Only one secretary, that of a small diocesan society, makes any general charge of laxity, but he gives no particulars. It may be fairly assumed from the replies that on the whole there has been no just cause of complaint against the profession. The charges, which have been freely made prior to this inquiry, appear to have been formulated merely for the purpose of discrediting the profession, with the view of having the appointment of paid certifiers given to certain societies at the public expense.

The Local Government Board and the Appointment of a Medical Officer of Health.

The Tobercurry union is a large area in county Sligo, with a population of between 19,000 and 20,000 persons. It includes a town and a wide country district, and town and country alike have for years past suffered from the ravages of typhoid fever, the source of which has not been discovered. The duties of medical officer of health are performed, each for his own district, by the four dispensary medical officers at salaries amounting in sum to £60 a year. The guardians have recently proposed to appoint a superintendent medical officer of health at a salary of £40 a year. This proposal seems to err, if at all, on the side of modesty, but this is not the opinion of the Local Government Board, without whose sanction the appointment cannot be made. The Board has written to the guardians, pointing out that if the appointment is made three-fourths of the expense must be borne by the ratepayers. Not content with this, it is added that if such an official be appointed the Board will insist on his residing within the union. This condition is impossible to fulfil, as there are already as many medical men resident in the union as can reasonably hope to make a living there, and even an Irish medical officer of health cannot live on £40 a year. The restriction is all the more absurd in that Tobercurry lies midway between two considerable wns, Sligo and Swinford, both of which are ithin easy reach by rail or motor.

Belfast Ophthalmic Hospital.

At the annual meeting of the friends of the lfast Ophthalmic Hospital held on March 16th, e report presented showed that 189 patients were mitted to the institution for treatment, while 21 eye cases and 769 ear, nose, and throat tients sought advice and treatment in the extern partment Financially the total income for the ar was £477 11s 3*d*, the expenditure £393 7s 6½*d*, ving a balance in hand of £84 3s 8½*d*

arch 24th

PARIS.

The Effect of Sunlight on Nutrition

r Laveran recently brought before the Académie Medecine some experiments made in Algeria by Miramond, of Laroquette, which tend to show t the sun's rays can determine in the tissues ain reactions of a nutritive character Guinea were enclosed in glass cases on the terraces of rian houses and received a fixed ration of rammes of oats for each 100 grammes of weight during the winter When the on was reduced to 3 grammes on days when sun was powerful the guinea pigs' weights ained exactly the same The author, who, how does not appear to have investigated whether animals underwent less muscular exertion the hot days, thus lessening physiological nditure, compared this fact with the well n view that the alimentary needs of the m are less in summer than in winter, in hot tes than in cold Certain natives of Southern na retain their weight on a diet equal to 1200 ies, while the European mean requirement is calories Dr Miramond concludes therefrom the increase in the solar rays compensates for eduction in the ration It may, however, be with equal reason that a part of the alimentary intended to maintain the animal heat nes useless when the external temperature s a reduction in the expenditure of energy

Rival Antityphoid Vaccines

two antityphoid vaccines—that of Professor temesse prepared from heated cultures of h s bacillus, and that of Professor Vincent, l de Grace, prepared from cultures of many of bacilli sterilised by ether—continue to their results reported before the Academie de ine Following on the reporting of M nt's results obtained in Morocco and in small mics in the garrisons of France, M Chantemesse ade known the results of inoculations with accines in the army and navy In the it is shown that 60,851 non vaccinated ave given 1354 cases with 174 deaths, while those vaccinated, who numbered 2644, there t been a single case and of course no death navy the success has been the same, in the number of 4698 inoculated sailors there has en a single case of typhoid fever, while the non inoculated furnished 580 cases with ths By means of this vaccination it has ossible to check at once threatened epidemics isons, in industrial towns, and in an insane Immunity is acquired only after four sive inoculations M Chantemesse asserts is vaccine has no unfavourable sequelæ ts up no other disease, thus suggesting n the case of M Vincent's vaccine the reaction is very severe and that it runs the risk of giving rise to other diseases in young soldiers recently recruited The Minister of War has provisionally suspended in the army until May vaccination with M Vincent's vaccine, in consequence of the poor hygienic condition of the troops during the past winter, through a rainy season, and often in extemporised barracks M Vincent has declared that these measures have been adopted in the interests of his vaccine, in order that it should not be accused of producing the troubles that have been noted this winter in a large number of soldiers Typhoid fever, too, is quite rare in the army at present, and in the solitary focus where it exists, the garrison of Tours, vaccination has been practised

A New Sanitary League

A new association has been instituted to make war on flies and other insects, rodents and other animals which transmit infectious diseases The organising meeting of the society was held at the Ministry of the Interior under the presidency of the Secretary of State The elected officers are President, Professor Blanchard, vice presidents, Dr Renaut and Professor Vincent, General secretary, M Richter, who is secretary of the permanent commission on house sanitation

Legal Responsibility of the Medical Practitioner

The Seventh Chamber of the Tribunal of Paris has rendered a judgment of great importance to the medical profession A child having succumbed to an angina, the father sued the doctor for 1500 francs damages for malpractice on the ground that he had not made a bacteriological examination and treated the child with diphtheria antitoxin After hearing long arguments and much expert evidence the court gave judgment against the plaintiff on the ground that though those methods of diagnosis and treatment were in every way admirable, the law could not impose their use because they were still open questions in the present state of science Medical responsibility for malpractice was limited to disregard of measures that were practically unanimously enjoined, in other matters the doctor was allowed to base his diagnosis and treatment on such measures as his conscience dictated On the other hand, a patient who sued before the Paris Tribunal his former doctor for 50 000 francs, on the ground that the doctor had treated him for an affection of the lungs when, as was afterwards proved, he was suffering from an intestinal disease, has been awarded 20 000 francs The medical syndicates will endeavour to have this judgment set aside, fraught as it is with the gravest possible consequences to the profession, for cases are by no means infrequent in which the diagnosis between an infectious pneumonia and typhoid fever remains for a considerable period doubtful

Obituary

Dr Launois has died suddenly from myocarditis consequent on an illness of three years duration He was 55 years of age, and had been physician to the Paris hospitals since 1887, and a *professeur agregé* at the Faculty of Medicine since 1889 He was physician to the Hopital Lariboisière He had published important works on histology and pathological anatomy As assistant to Professor Mathias Duval he had acted as his substitute during the latter s last years, and on his death it seemed certain

but at that tin

the nomination

Industrial Alcohol Association has suggested placing wood alcohol under rigid supervision by the Internal Revenue, subject to a tax of from 2 to 10 cents per gallon, according to the degree of refinement. Partially refined wood alcohol carries in its obnoxious odour a warning against its use, but completely refined and deodorised wood alcohol (methyl) can be distinguished from pure grain alcohol (ethyl) only by expert tests. It is suggested that the law should also provide that wood alcohol must be labelled "Poison."

Pasteurisation of Milk to be Compulsory in New York City.

The recently appointed Commissioner of Public Health for New York City, Dr. Goldwater, has determined to enforce the order of the New York Board of Health adopted some time ago with regard to the pasteurisation of all grades of milk except the certified and guaranteed.

Restriction of Immigration.

Much dissatisfaction has long existed with regard to the manner in which unfit immigrants are allowed to enter the United States. A large proportion of inmates of insane asylums, and especially of those in New York State, have been found to be of alien birth. It is now proposed to add further amendments to the pending Immigration Bill, and several medical men and representatives of civic organisations have been summoned to appear before the committee. It is suggested that not only the insane but persons of "constitutional psychopathic inferiority" and chronic alcoholics shall be excluded. The period in which an alien who becomes a public charge may be deported is also to be extended from three to five years.

Scarlet Fever in New Jersey.

Recently there has been much scarlet fever in New Jersey, and an epidemic is now raging in the town of Florence. Twelve persons have died from it, and schools, churches, moving pictures exhibitions, and all places of public gathering have been closed. The epidemic is of a virulent type.

Small-pox.

Since Feb. 25th three districts of Philadelphia have been quarantined against the spread of small-pox, and more than 4000 persons have been vaccinated. The disease is believed to have been imported from Baltimore. The town of Niagara Falls has long been strongly antivaccinationist, and in consequence is not infrequently visited by outbreaks of small-pox. There are now 105 cases of small-pox there; 39 houses there are under quarantine, and 22 patients are being treated in the quarantine hospital. Cases of small-pox were reported from nine towns in the western part of New York State, all of which were traced directly to Niagara Falls. The order of Dr. Hermann Biggs, the new Health Commissioner of New York State, that the population of Niagara Falls be vaccinated has aroused great opposition.

Death of Dr. William Kelly Simpson.

Dr. William Kelly Simpson, professor of laryngology in the College of Physicians and Surgeons, Columbia University, New York, died recently. Dr. Simpson was born in Hudson, New York, in 1855. He graduated in Arts at Cornell University in 1876 and in medicine at the College of Physicians and Surgeons of New York in 1880. He became assistant professor of laryngology in 1892 and professor in 1904. He held many hospital appointments and was a member of many medical societies. Dr. Simpson was eminently successful both in practice and as a teacher, and was a man of great charm.

March 16th.

SOUTH AFRICA.

Death of a Well-known Rand Practitioner.

THE death occurred recently in Johannesburg of Dr. Johnstone Brown, who came out to South Africa in 1896 and commenced practice at Ficksburg in the Orange Free State. On the outbreak of the Boer war he was taken prisoner by General de Wet, but escaped. He then joined the British forces and was present at several engagements, notably Wepener, where he rendered splendid services to the wounded of both sides. At the conclusion of the war he commenced practice in Johannesburg, and soon acquired an extensive connexion. At the time of his death he was senior physician to the Johannesburg Hospital and medical adviser to several friendly societies. He was also honorary treasurer of the Witwatersrand Branch of the British Medical Association. He will be greatly missed, not only in professional circles, where he was beloved, but by a host of patients and friends.

Spread of Syphilis in South Africa.

Syphilis appears of late to have been spreading rapidly amongst the native races of South Africa. In the Transvaal and the northern districts of the Cape most native races are thoroughly infected; also in the Transkeian territories, though to a less extent. In Natal the disease is beginning to play havoc with the Zulus —perhaps the finest native race in South Africa. District surgeons are permitted to attend native patients at Government expense, but no control is exercised to see that they are attended or are kept under treatment when once placed on the register. The fees paid in the different provinces are small. Instances of European children having become infected from native nurse girls are of not infrequent occurrence, and adequate measures for the control of the disease are imperatively called for. A deputation from the United Municipal Association of South Africa waited upon the Prime Minister a few months ago, but got no satisfaction beyond the stereotyped reply that the matter would receive the consideration of the Government. It is to be hoped that steady pressure will be kept on the Government to induce it to appoint a Commission to deal with this question.

The Great Strike.

The railway strike has come and gone. It had been expected for many months, and when it came and the Federation of Trades proclaimed simultaneously a general strike of all trades the action of the Government in calling out the active citizen force and in the northern provinces the burghers, and in proclaiming martial law in those provinces and in Natal, foredoomed it to failure. The Medical Department of the Defence Force played its part in the recent mobilisation, but in the event of casualties it would assuredly have broken down, and the Government would have had to rely upon the civil organisations and hospitals. Fortunately, there were no casualties worth speaking of and the Government will doubtless realise that, however efficient the Defence Force is as a whole, the medical department needs strengthening. The need for the appointment of a suitable officer as Director of Medical Services should be apparent to

. The work cannot be done efficiently by a non- ofessional officer even when the latter is advised such an efficient professional officer as the esent staff officer for medical services, Major ock. So far as the intentions of the Government ve been announced, it is only proposed to ask rliament to pass an Indemnity Bill and necessary ancial measures during the present session. It expected, however, that the medical members ll insist upon the conditions on the mines being ought under review, and particularly the working the Miners' Phthisis Compensation Act, which been responsible for much criticism. Also it uld seem likely that an effort will be made to get Government to establish a definite Medical partment responsible for health conditions on mines, and also for the medical treatment of ne natives. The present system of part-time dical officers under the control of, and paid by, mining houses themselves has failed, and it is that the State should step in without further ay and establish a sound organisation to take trol and enable the workers on the mines to feel t Government is rendering their calling less gerous and striving to reduce the present alling death-rate.

Rhodesian Nursing Service.

n view of the shortage of nurses in South ica the Government of Southern Rhodesia organised a scheme which it is hoped will l to its hospitals being supplied with a icient number of probationers and trained ses. The service is managed by a chief matron is stationed at Salisbury under the general ervision of the Medical Director. The chief ure in the service is the terms upon which bationers are engaged. They receive £35 for first year, £40 for the second year, and £45 per um thereafter. This liberal remuneration is, course, due to the fact that Rhodesia still has to ruit most of its probationers from other parts of th Africa. Trained nurses receive £60 per um, which is less than they receive at many pitals in the Union, but as against this is the t that after ten years' service—five of which e to be passed as a matron—nurses in the vice are eligible to join the fixed establishment l receive a pension on retiring, which varies ording to the salary that they have previously n drawing.

b. 4th.

Obituary.

RANCIS HENRY HAWKINS, M.D., C.M. EDIN., M.R.C.P. LOND.,

LATE PHYSICIAN TO THE ROYAL BERKSHIRE HOSPITAL.

Dr. Francis Hawkins, of Reading, died suddenly his house on Feb. 26th. He had a serious illness ne years ago, and his health since then had been paired, but the news of his death came as a rprise.

Francis Henry Hawkins was the third son of the e Henry John Hawkins. He received his medical ucation at the University of Edinburgh, at Uni- rsity College, London, and at Vienna and Berlin. e obtained the M.B. and C.M. degrees at Edinburgh 1882 and the M.D. degree in 1899, and in the llowing year took the Membership of the Royal llege of Physicians of London. His early appointents included those of demonstrator of phys in the medical school of Charing Cross Hospital, resident physician to the Edinburgh Royal Infirmary, and house physician to the Brompton Hospital. Then for a time he was physician to the North London Hospital for Consumption and physician to out-patients at the Hospital for Epilepsy and Paralysis.

Going to Reading as a consulting physician, Dr. Hawkins was appointed about 20 years ago to the medical staff of the Royal Berkshire Hospital, and only resigned his post as physician last December. In addition to his hospital work and private practice he was examining physician to the National Hospital for Consumption, Ventnor, and a lieutenant-colonel in the Royal Army Medical Corps (Territorial Force), and was a medical referee under the Workmen's Compensation Act. He had also been president of the Windsor Medical Society and was a prominent Freemason. He made a number of communications upon professional subjects to medical journals, including a paper on ascites printed in the Proceedings of the Royal Society of Medicine in 1908. Soon after settling in practice at Reading Dr. Hawkins married Louisa Maud, daughter of the late Colonel Alexander Maclean, of Coll. He leaves five children, the eldest a boy of 17. The funeral took place at Welford, near Newbury, on March 3rd, the first part of the service being held at St. Giles's Church, Reading, where Dr. Hawkins had long been a member of the congregation.

NATIONAL SOCIETY OF DAY NURSERIES.—This society was founded in 1906 to promote organised efforts to found day nurseries for the health and protection of young children, to help conduct them on model lines, and to train nurses. The society aims at providing every crowded factory district of Great Britain with a public day nursery, where the children of mothers who are compelled to go out to work may be carefully nurtured, at a small charge per child, amid cheerful and happy surroundings, secure from the dangers of the street and injury. Abroad official grants are given to such nurseries both by the State and other public bodies, but in Britain the crèches or public nurseries are still entirely dependent upon voluntary contributions. The society's secretary and offices are at 4, Sydney-terrace, Fulham-road, London, S.W.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on March 19th, with Sir Francis H. Champneys in the chair. A letter was considered from the county medical officer of health for Herefordshire calling the attention of the Board to the attitude of the magistrates of the Ross Petty Sessional Division in dealing with a case where an uncertified woman was prosecuted by the county council for an infringement of Section 1 (2) of the Midwives Act, 1902. The Board directed that the matter be referred to the Privy Council and that the chairman be asked to communicate with the clerk of the Council on the subject. A letter was considered from the clerk of the county council of Hampshire inquiring whether, with a view to obtaining notification of stillbirths in all cases, the rules could be so amended as to provide that the bodies of stillborn children should not be disposed of without a medical certificate following upon an examination of the body. The Board decided that the matter be considered at the next revision of the rules. A letter was also considered from the county medical officer of health

the desirability of granting furth

of midwives within the county.

county medical officer of heal.

informed that the Board considers that the standard of training requires raising at the earliest opportunity, and is not prepared to consider any proposal for lowering that obviously absent in cooked food; no wonder, then, that the idea has got abroad that cooked food cannot contain vitamines, just because of the confusion that has arisen from one word being used in two quite different senses.

I am, Sir, yours faithfully,
W. D. HALLIBURTON.
King's College, London, March 21st, 1914.

ACUTE SUPPURATIVE OTITIS MEDIA IN SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—The question raised by Dr. J. Mackern in your issue of March 21st—viz., how long an otorrhœa arising in connexion with scarlet fever is capable of retaining its infectivity—is one of considerable importance. Unfortunately, it is one to which it is impossible to reply categorically. Since we are still in ignorance as to the identity, or even the nature, of the infective agent in scarlet fever, even the most careful examination of the ear discharge must needs fail completely to yield any direct evidence as to its infectivity

In coming to a decision, therefore, as to when it is safe to release from isolation a person who has recently had scarlet fever and whose ear is still discharging, we have, perforce, to fall back upon inferences based partly on the relationship observed to exist between otorrhœas of varying degrees of persistence and their apparent capacity to infect, and partly on the results obtained by following out our beliefs in practice. That the infection in scarlet fever attaches especially to the mucous membranes and their discharges rather than to the desquamating cuticle is now being generally recognised, traditional beliefs notwithstanding; but that a nasal discharge, particularly if of a purulent character, is far more potent for harm than a discharge from the middle ear is not, perhaps, so widely recognised.

My own experience does not lead me to regard with much apprehension the presence of an otorrhœa in a patient who has undergone the usual period of isolation, in the absence of any nasal discharge and of any marked relaxation of the fauces. The relative importance of a nasal discharge has been clearly demonstrated by the investigations into the origin of "return cases" of scarlet fever and diphtheria which were carried out some years ago on behalf of the Metropolitan Asylums Board. Dr. A. G. R. Cameron showed that, as regards scarlet fever, amongst the "primary infecting cases," 648 in number, which fell within the scope of his inquiry, rhinorrhœa was present in 52·3 per cent., whereas otorrhœa was present in but 8·3 per cent. In a good many of the latter a morbid condition of the nasal mucosa existed as well and furnished a more likely source of infection. That an otorrhœa arising in connexion with scarlet fever is infectious for a time is more than probable, but when it ceases to become so is impossible to ascertain, owing to our ignorance of the specific causative agent. Any dogmatic assertion on the point should be mistrusted. The period of infectivity, however, doubtless varies in different cases.

Although formerly insisting on a 12-weeks' isolation, a close acquaintance with scarlet fever, extending over more than a quarter of a century, has convinced me that, if the faucial and nasal mucosa are healthy, a patient may be released at the expiration of eight weeks with comparative safety. Nearer than this one cannot go in view o those occasional cases of scarlet fever in which the patient's infectivity is unduly protracted withou there being apparent any sign by which its presence might be suspected. So long as an otorrhœ persists the use of an antiseptic lotion and th careful disposal of anything liable to be soiled b the discharge are common-sense precautions.

I am, Sir, yours faithfully,
F. FOORD CAIGER.
South-Western Hospital, Stockwell, S. W., March 23rd, 1914.

SYPHILIS AND "MENTAL DEFICIENCY.

To the Editor of THE LANCET.

SIR,—We have read with much interest th letter of Sir H. Bryan Donkin in your issue March 14th on syphilis and mental deficiency. A your readers must heartily agree with him th the greatest caution requires to be exercised in th observation of facts and in the method of inte preting them before making public any doctrine implication that syphilis is a predominant cause mental defect generally. Sir Bryan Donkin the goes on to say that the conclusion which w expressed in our paper,[1] based on the examination 205 cases, that syphilis is the causative factor in very considerable percentage of cases of ment deficiency of whatever grade of severity as it present in over 50 per cent., is "wholly unwarrant by the facts adduced." He appears to base th criticism of our results largely on his statement th there has been hitherto, so far as he is aware, " attempt made to ascertain the frequency of positi reactions to the test in the blood of large numbe of individuals of similar conditions to those co posing the special groups *under investigation*, b to whom 'mental defect' cannot be attribute At the time of writing our paper we were actual in possession of such evidence regarding t percentage of positively reacting children similar age and social state, but without ment defect, which had been obtained in the course the examination of over 1000 children by one us (H. F. W.); but in view of the very hi association of syphilis with mental deficiency a epilepsy we did not imagine that the figur could fail to carry conviction to any one. summary of these control observations of one us (H. F. W.) was subsequently published in I Carl H. Browning's paper,[2] but it appears to ha escaped Sir Bryan Donkin's notice; the resul obtained were that out of 331 mentally norm children belonging to the same age and class grou who were attending the dispensary of the Ro Hospital for Sick Children and the Central D pensary, Glasgow, and who were not suffering fro frankly syphilitic conditions, 10 per cent. react positively in the Wassermann test. An entire independent observer, Dr. Elliot, who recent reported to the Glasgow Medico-Chirurgical Socie the results of the examination of a similar group 127 children in the measles and whooping-cou wards of Ruchill Fever Hospital, obtained positi reactions in 8·6 per cent. of cases. These resul correspond well with the figure (8·7 per ce of positives) in a small series of apparently norm school children, published by one of us (K. F.). way of contrast and as demonstrating the reliabili of the Wassermann test, it may be mentioned th in a group of 433 cases in which syphilis w cluded as far as possible by clinical methods only ; cases reacted positively, and of these 6 came om one family. Our results in 205 cases of mental ficiency and epilepsy have thus been controlled ; the observations of Dr. Elliot and of ourselves a series of 481 children belonging to the same ;e and class groups, from which it appears that nong mental defective and epileptic children in lasgow the incidence of syphilis is proved to be at ast five or six times as great as among children average intelligence. In view of these figures o find it difficult to understand how our conclusion garding the rôle of syphilis in mental deficiency id epilepsy can be avoided. With regard to the servations of workers in foreign countries we ive no comment to offer; we would only emphasise e fact that *all our cases were children*, since ean has drawn attention to the absence of positive action in cases of congenital syphilis after 16 years age. We would also draw attention to the fact, owever, that another worker here, Chislett, at oodilee Asylum, Lenzie, obtained 35 per cent. of sitive reactions in his series of 26 cases belonging this group.[3] Thus the sum total of results in is country bears out the statement of Browning d McKenzie that "syphilis plays a larger part congenital mental affections than is genelly supposed. ...... If medical science is prepared urge prophylactic measures for the prevention such diseases, it is well that it should be finitely established and recognised that a conlerable proportion of cases of congenital mental ficiency are of infective origin and that the fection is syphilis."

HANGES IN THE BLOOD IN SURGICAL SHOCK.

To the Editor of THE LANCET.

SIR,—In his very interesting Hunterian lecture iblished in THE LANCET of March 14th Mr. A. endle Short repeatedly mentions the difficulty understanding how a fall of blood pressure in be associated with a normal heart action id contracted peripheral arteries. He very ndly credits me with having long maintained e view that the arteries are contracted in shock, hich view he accepts at least in so far as the eripheral arteries are concerned. He therefore jects Crile's theory of vaso-motor paralysis, and he jects also the "acapnia" theory, the "oligæmia" eory, and the "suprarenal exhaustion" theory. y a process of exclusion he is driven "to return to e central nervous system" to seek "an explanaon of a falling blood pressure with a normal heart nd vaso-motor centre and contracted peripheral rteries."

I do not propose to make any comment upon the xplanation which Mr. Short suggests, but I should ike to be allowed to endeavour to persuade him to econsider his conclusion regarding oligæmia. He ays that "if the total blood volume were reduced *oligæmia* = scanty blood) the blood pressure would all and yet the heart and vaso-motor centre might ct well and the arteries be constricted." He, owever, rejects the view that the total blood olume is reduced, because he did not find that t pecific gravity of the blood showed any rise in certain cases of shock which he studied, and in one patient, to whom a pint of saline and glucose had been given, there was a fall of the specific gravity of the blood. Sherrington and Copeman came to an opposite conclusion—namely, that the specific gravity of the blood rises in the state of shock, and, as Mr. Short says, I accepted their statement because it so clearly harmonises with clinical facts. Apart from variations in the specific gravity of the blood, I would point out that in well-marked shock the peritoneum is as pale and bloodless as the skin, an assertion fully corroborated by Crile. I cannot agree with Mr. Short's statement that the abdominal veins are dilated in shock. In fact, a chief characteristic of shock is the bloodlessness of the tissues everywhere, and therefore it seems to me impossible to avoid the conclusion that the blood somehow gets out of the vessels. When in addition it is observed that the patient is sweating freely the evidence seems conclusive. I think it highly probable that serum escapes primarily and that the specific gravity of the blood does tend to rise, but when I first wrote on this subject I pointed out that there are indications that the solid parts of the blood are also destroyed in excessive amount in the state of shock—to wit, for example, the bilious vomiting so commonly observed. Hence I would not pin my faith to a raised specific gravity of the blood as a necessary effect of its diminished volume, and particularly in clinical cases, in which there may be many complicating conditions, this consideration might lead to error. It must be remembered also that hæmorrhage tends to *lower* the specific gravity of the blood. I am, therefore, not persuaded that Mr. Short's evidence justifies his conclusion that it is "quite clear that oligæmia cannot be the essential factor in shock." I do not claim such importance for the condition, but it seems to me quite certain on clinical evidence alone that the amount of blood in the vessels diminishes as shock develops, and I think that Mr. Short might well revise his decision on this point.—I am, Sir, yours faithfully,

Wimpole street, W., March 21st, 1914. JOHN D. MALCOLM.

CHOLESTEROL ANTIGEN IN WASSERMANN'S REACTION.

To the Editor of THE LANCET.

SIR,—So long as the discussion upon the uses and abuses of cholesterol in the Wassermann's reaction remains scientific and becomes no personal matter perhaps some real good may result. At the present moment a subcommittee is sitting to discuss the relative merits of the various ingredients and modifications of the Wassermann's reaction; useless as it may be any *additional* knowledge can do no harm. Before the *relative* merits of the ingredients and *modifications* of the Wassermann's reaction are given any consideration whatever, the *rationale* of the reaction should be understood; not until the empiricism is removed can any good result from an inquiry. *It follows* from this that the addition of any new *substance*, such as cholesterol to the antigen, is *only another* step into the dark; indeed, it is *a* hindrance and not an advance. For the last two years I have been trying to fathom the cause of the

in so doing have *out* sever

ith cholesterol, a h I

few remarks.

patient's

obviously absent in cooked food; no wonder, then, that the idea has got abroad that cooked food cannot contain vitamines, just because of the confusion that has arisen from one word being used in two quite different senses.

I am, Sir, yours faithfully,
W. D. HALLIBURTON.

King's College, London, March 21st, 1914.

ACUTE SUPPURATIVE OTITIS MEDIA IN SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—The question raised by Dr. J. Mackern in your issue of March 21st—viz., how long an otorrhœa arising in connexion with scarlet fever is capable of retaining its infectivity—is one of considerable importance. Unfortunately, it is one to which it is impossible to reply categorically. Since we are still in ignorance as to the identity, or even the nature, of the infective agent in scarlet fever, even the most careful examination of the ear discharge must needs fail completely to yield any direct evidence as to its infectivity

In coming to a decision, therefore, as to when it is safe to release from isolation a person who has recently had scarlet fever and whose ear is still discharging, we have, perforce, to fall back upon inferences based partly on the relationship observed to exist between otorrhœas of varying degrees of persistence and their apparent capacity to infect, and partly on the results obtained by following out our beliefs in practice. That the infection in scarlet fever attaches especially to the mucous membranes and their discharges rather than to the desquamating cuticle is now being generally recognised, traditional beliefs notwithstanding; but that a nasal discharge, particularly if of a purulent character, is far more potent for harm than a discharge from the middle ear is not, perhaps, so widely recognised.

My own experience does not lead me to regard with much apprehension the presence of an otorrhœa in a patient who has undergone the usual period of isolation, in the absence of any nasal discharge and of any marked relaxation of the fauces. The relative importance of a nasal discharge has been clearly demonstrated by the investigations into the origin of "return cases" of scarlet fever and diphtheria which were carried out some years ago on behalf of the Metropolitan Asylums Board. Dr. A. G. R. Cameron showed that, as regards scarlet fever, amongst the "primary infecting cases," 648 in number, which fell within the scope of his inquiry, rhinorrhœa was present in 52·3 per cent., whereas otorrhœa was present in but 8·3 per cent. In a good many of the latter a morbid condition of the nasal mucosa existed as well and furnished a more likely source of infection. That an otorrhœa arising in connexion with scarlet fever is infectious for a time is more than probable, but when it ceases to become so is impossible to ascertain, owing to our ignorance of the specific causative agent. Any dogmatic assertion on the point should be mistrusted. The period of infectivity, however, doubtless varies in different cases.

Although formerly insisting on a 12-weeks' isolation, a close acquaintance with scarlet fever, extending over more than a quarter of a century, has convinced me that, if the faucial and nasal mucosa are healthy, a patient may be released at the expiration of eight weeks with comparative safety. Nearer than this one cannot go in view of those occasional cases of scarlet fever in which the patient's infectivity is unduly protracted without there being apparent any sign by which its presence might be suspected. So long as an otorrhœa persists the use of an antiseptic lotion and the careful disposal of anything liable to be soiled by the discharge are common-sense precautions.

I am, Sir, yours faithfully,
F. FOORD CAIGER.

South-Western Hospital, Stockwell, S.W., March 23rd, 1914.

SYPHILIS AND "MENTAL DEFICIENCY."

To the Editor of THE LANCET.

SIR,—We have read with much interest the letter of Sir H. Bryan Donkin in your issue of March 14th on syphilis and mental deficiency. All your readers must heartily agree with him that the greatest caution requires to be exercised in the observation of facts and in the method of interpreting them before making public any doctrine or implication that syphilis is a predominant cause of mental defect generally. Sir Bryan Donkin then goes on to say that the conclusion which we expressed in our paper,[1] based on the examination of 205 cases, that syphilis is the causative factor in a very considerable percentage of cases of mental deficiency of whatever grade of severity as it is present in over 50 per cent., is "wholly unwarranted by the facts adduced." He appears to base this criticism of our results largely on his statement tha there has been hitherto, so far as he is aware, "n attempt made to ascertain the frequency of positiv reactions to the test in the blood of large number of individuals of similar conditions to those composing the special groups *under investigation*, bu to whom 'mental defect' cannot be attributed. At the time of writing our paper we were actuall in possession of such evidence regarding th percentage of positively reacting children c similar age and social state, but without menta defect, which had been obtained in the course of the examination of over 1000 children by one of us (H. F. W.); but in view of the very high association of syphilis with mental deficiency and epilepsy we did not imagine that the figures could fail to carry conviction to any one. A summary of these control observations of one of us (H. F. W.) was subsequently published in Dr. Carl H. Browning's paper,[2] but it appears to have escaped Sir Bryan Donkin's notice; the results obtained were that out of 331 mentally normal children belonging to the same age and class groups, who were attending the dispensary of the Royal Hospital for Sick Children and the Central Dispensary, Glasgow, and who were not suffering from frankly syphilitic conditions, 10 per cent. reacted positively in the Wassermann test. An entirely independent observer, Dr. Elliot, who recently reported to the Glasgow [illegible] Society the results of the examin[illegible] group of 127 children in the measles and whooping-cough wards of Ruchill Fever Hospital, obtained positive reactions in 8·6 per cent. of cases. These results correspond well with the figure (8·7 per cent. of positives) in a small series of apparently normal school children, published by one of us (K. F.). By way of contrast and as demonstrating the reliability of the Wassermann test, it may be mentioned that in a group of 433 cases in which syphilis was ndents, and questions whether the benefits of services of such practitioners might be nately extended to others in better circum- ces. One might as well question whether the fits of the elementary schools might be ex- ed to the upper classes, or the benefits of the law medical service to well-paid artisans. If whole-time salaried service were really the boon manity that Mr. Parker and others believe it e, should we not find it being first intro- d for the benefit of the rich and later being nded to the poor? When the mover and seconder Bill for the establishment of a whole-time ical service, be they members of the Labour y or any other party in Parliament, explain they for themselves and their wives and lies are expecting to make use of the benefit provided, the scheme might be regarded as in the range of practical politics. The present mes for establishing such a service are really osals made by superior persons for the good of "lower orders," whose poverty would alone el them to submit to the discipline of State cal officials, a discipline from which our legis- s themselves and the wealthy classes generally ld secure freedom by the payment of money. Parker quotes with satisfaction a recent ion of the High Court that a parent might mprisoned for refusing to submit his child to rgical operation recommended by a doctor. Mr. Parker imagine that a High Court judge ever have the opportunity of imprisoning or g a peer or a member of the House of mons for not allowing a surgeon to remove child's adenoids or a bacteriologist to inject it a tuberculin? If a judge is found on appeal to higher court to have the power at the present to deal out justice of this sort to the poor can be little doubt that further legislation in due time deprive him of it.

[2] Brit. Med. Jour., Jan. 10th, 1914.

would be a good criterion of the value of any ested legislation in connexion with medicine to ider whether we are proposing to extend leges already possessed by the independent es to those who are in poverty, or to set up for in straitened circumstances so-called benefits hich the wealthy classes would never avail nselves. Measured by such a test the whole- salaried medical service will, I believe, be rded by the great majority of the public and profession as unacceptable.

have no scruples in thus pointing out to that his panacea for all medical evils is icable, for I am sure I can show him that real improvements he desires are attain- endently of his cherished whole-time tor on a panel can refer his patient t, a specialist, or a bacteriologist, just profitably as could a member of a . The provision of sufficient tion throughout the kingdom, essible to all classes who want be, of the State in securing ust depend upon the to the wards being rvant of the State. rsons and others sities are already y philanthropic voluntary hos- for consider- systematic to is almost certainly necessary in many directions. A chief obstacle to the attainment of these desirable aims is the clamour of a small section of reformers who insist, in season and out of season, that the only possible way of remedying existing evils is the quite impossible way of transforming all that part of the profession which treats the industrial classes into a State service of whole-time salaried officers.

No one stops progress so much as he who insists that the impracticable must first be achieved.

I am, Sir, yours faithfully,

Harley-street, W., March 15th, 1914. LAURISTON E. SHAW.

THE MILWARD FUND: A LETTER OF THANKS.

To the Editor of THE LANCET.

SIR,—Will you allow me, through THE LANCET, to express a little of the gratitude I feel to all those who have so generously helped me and my boys in our need?

Of the practical sympathy shown us, you have just published some of the material results; and only those with children to equip for their work in life can realise the load of responsibility of which I have been relieved by the assurance of good education for my boys, and of the means to meet their expenses during their apprenticeships.

I cannot hope to express adequately my appreciation of this, and even less can I do so of the constant reminders of sympathy and encouragement that so many have given us since our loss.

I can only trust that our gratitude may meet with the same understanding that our many friends have shown us in our sorrow.

Believe me, yours faithfully,
E. S. DOROTHY MILWARD.

5, Glossop-road, Cardiff, March 21st, 1914.

AN ASSOCIATION OF TUBERCULOSIS MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—The letter on the above subject in your issue of March 21st suggests to me four points:—

1. Sanatorium and consumption hospital residents and pathologists to be included. There would then result an association somewhat like the German one of *Tuberkulose Aerzte*, excellent reports of whose meetings reach one from time to time. It must be confessed that some tuberculosis officers have been appointed upon insufficient experience and scarcely know their subject.

2. None but "tuberculosis whole-timers"—i.e., those who deal with no other disease—to be eligible for any sort of membership.

3. Coöperation with the existing Irish association to be ted in every possible way, perhaps later by establish- [illegible] be [illegible] or [illegible] ttee [illegible] s of [illegible] and general management.

I enclose my card and remain, Sir,
Yours faithfully,
TUBERCULOSIS OFFICER.

March 23rd, 1914.

VICTORIA HOSPITAL, FROME.—It has been decided to carry out extensions and improvements at this hospital in order that the institution may be placed on the official list of the Somerset County Insurance Committee, and thus be in a position to treat patients suffering from tuberculosis. The cost of the scheme is estimated at £1250.

to him to associate with the toast the name of a former much-beloved pupil who had brought considerable credit on his old Cork *alma mater* by his distinguished services to science and the nation. The President, in reply, said he felt it a great honour to be placed in a chair which had been filled by such well-known members of the profession as Lord Ilkeston, William MacCormac, Richard Quain, Sir William Whitla, Professor Alexander Macalister, Sir Alfred Keogh, and Dr. Macnaughton-Jones. During the evening it was announced that the Arnott gold medal had this year been awarded by the council to Dr. A. Launcelot Hoops, a State surgeon in the Malay Peninsula, for his heroism in endeavouring to save the life of a boy who fell into the river Liffey.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The House of Commons and Housing.

Housing questions have recently been prominently before the House of Commons, and although the atmosphere of party surrounds the solutions of some aspects of the problem, it is common ground that from the public health point of view much requires to be done both in the direction of erecting new houses and in dealing with existing insanitary dwellings. A discussion on the problem took place on Friday, March 20th, on the Housing of the Working Classes Bill, the second reading of which was moved by Sir A. Griffith-Boscawen. It may be noted at the outset from the narrower medical aspect that one of the most important announcements made in the course of the debate was that the Government was giving earnest attention to the question of the security of the positions of medical officers of health and sanitary inspectors.

The Bill is promoted by members on the Opposition side of the House. Sir A. Griffith-Boscawen indicated the three principles on which it proceeded. The first was that the housing evil was so great that the nation must step in and shoulder part of the burden; the second was that the State should work through the local authorities; and the third was that although State and municipal provision was necessary, private enterprise must continue to do the biggest share. With regard to the country, the Bill provided that where houses could not be built to be let at rents which the poorest could afford to pay, the State should bear a portion of the cost. In the subsequent debate much was heard about the evils to health which arise from overcrowding and insanitary dwellings. Some objections were taken to the Bill on the Ministerialist side on the ground that it would provide a "subsidy" to landowners.

Mr. Herbert Samuel, the new President of the Local Government Board, fully admitting the gravity of the problem of housing, urged a number of financial considerations against the precise proposals of the Bill. He intimated that he had taken steps to set on foot a housing survey with a view to ascertain the number of houses unfit for habitation and the number of those which, while not absolutely unfit, were unhealthy and required structural alterations. Amongst the proposals which the Government favoured to provide a remedy were the enactment of a minimum wage and the relief of rating upon housing and improvements. He also looked to the improvement in methods of transit to spread the population over a larger area. It was desirable to remove restrictive building by-laws, and the Parliamentary Secretary of the Local Government Board had accepted the duty of acting as chairman of a Departmental Committee to go into this question and to make suggestions for legislative and administrative action. The report of the Departmental Committee on Local and Imperial Taxation would be published in a few days. It would be found that amongst their proposals would be a suggestion that there should be a grant from the Central Exchequer to all local authorities to assist them to deal with questions of public health. The grant, it was suggested, should be based upon population and should be conditional upon the due performance of their duties in respect to public health. He was not in a position to pledge the Government with regard to that, for it had not yet come under the consideration of the Treasury. Amongst other matters the security of the positions of medical officers of health and sanitary inspectors was receiving the earnest attention of the Government. They were also considering a number of minor amendments of the Housing Acts.

The Bill was read a second time, without a division.

HOUSE OF COMMONS.

Wednesday, March 18th.

Grants for the Treatment of Tuberculosis.

Mr. Astor asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners—(1) whether any councils of counties or county boroughs ha agreed, under Section 17 of the National Insurance Act, 1911 to pay half of any expenditure on the treatment of tuberculous insured persons over and above the money provide for sanatorium benefit under Section 16 of the same Act and, if so, whether he would give the names of thos authorities in England, Scotland, Ireland, and Wale respectively who had agreed to such expenditure; an (2) whether any Insurance Committees had under Sectio 17 (2) of the National Insurance Act, 1911, transmitted to th Treasury and the councils of counties or county boroughs an communication or account showing that the amount available for defraying the expenses of sanatorium benefit t insured persons resident within their area was alread or was likely to be insufficient to meet such estimate expenditure; and, if so, whether he would give thei names.—Mr. Wedgwood Benn wrote in reply: Th arrangement by which the Treasury is prepared to mee one-half of the annual net cost to a local authority of scheme for the treatment of tuberculosis among the whol population of the area has provided an alternative to procedure under Section 17 (2) of the National Insurance Act 1911, which alternative has been widely adopted by loca authorities. In England, though procedure under Sectio 17 (2) has in a few instances been at first suggested, th alternative method of a Treasury grant towards the cost of *comprehensive scheme is generally preferred, and in no* cas has Section 17 (2) been put into operation. A grant unde the subsection has been sanctioned in the case of thre counties and nine burghs in Scotland and in the case of on county in Ireland. All the counties and county boroughs i Wales with one exception have agreed to contribute out o the rates to the Welsh National Memorial Association.

Treatment of Tuberculous Persons.

Mr. Herbert Samuel (President of the Local Government Board), replying to Mr. Astor, wrote: According to special return obtained in November, 1911, there were a. that time 6908 cases of pulmonary tuberculosis and 1946 cases of other forms of tuberculosis under treatment in Poor-law institutions in England and Wales. There are no later figures available.

Mr. Hume Williams asked the right honourable gentleman in how many sanatoriums provided under the National Insurance Act for the treatment of tuberculous patients non-insured persons were being or had been treated, and where these sanatoriums were situated.—Mr. Herbert Samuel (in a written answer) replied: As regards England, all the sanatoriums the provision of which is being aided by grants from the Local Government Board will be available not only for those insured under the National Insurance Act, but also for the non-insured; and the other sanatoriums which have been approved under the Act for the reception of insured persons are also generally being used for non-insured persons as well. In regard to the last part of the question, perhaps I may refer the honourable Member to the return of approved sanatoriums presented to Parliament last autumn. The information contained in the return was brought up to date at the end of January, and I am sending the honourable Member a copy of the revised list.

Mr. Hume Williams also asked the right honourable gentleman whether in some institutions in which tuberculous patients were being, or had been, treated under the National Insurance Act, patients suffering from other and infectious diseases were, or had been, treated at the same time under the same roof, and not only in separate pavilions; and, if so, which were these institutions.—Mr. Herbert Samuel wrote in reply: Proposals were submitted to the Local Government Board in the case of five institutions to use for the treatment of tuberculosis, under the National Insurance Act, a portion of a building the other portion of which might be required in emergency for the treatment of other infectious diseases. In these cases temporary approval was given either on condition that the tuberculous patients would be removed if cases of other infectious diseases were received in the building, or on other conditions which I am advised sufficiently safeguarded the patients against risk of infection. The institutions in question are the infectious diseases hospitals belonging to the corporations of Blackpool, Winchester, Hastings, and Hove, and the urban district council of Barnes. In the case of the last three hospitals arrangements have now been made whereby a whole pavilion is set aside for the treatment of tuberculosis.

Insured Persons and Non-Pulmonary Tuberculosis.

Replying to Mr. Astor, Mr. Wedgwood Benn said: The sanatorium benefit return in course of preparation will show the number of insured persons suffering from non-pulmonary tuberculosis who have applied for and received treatment.

Insured Persons and Homœopathic Practitioners.

Mr. Wedgwood Benn informed Mr. Montagu Barlow that it was open to an insured person who desired the services of a homœopathic doctor not on the panel to apply to the Insurance Committee for leave to make his own arrangements for the purpose.

Mount Vernon Hospital.

Mr. CHANCELLOR asked the Chancellor of the Exchequer whether he had received the resolution passed at a public
town-hall on March 10th, which
f the Mount Vernon Hospital for
and would he state what action
matter.—Mr. WEDGWOOD BENN

MONDAY, MARCH 23RD.

Treatment of Tuberculous Persons.

Mr. CASSEL asked the Prime Minister whether the Government would introduce legislation to enable the expenditure incurred in treating insured persons suffering from tuberculosis in workhouse infirmaries to be recouped to the ratepayers.—Mr. ASQUITH replied: The question of the treatment of tuberculous insured persons is receiving consideration, but the Government have no intention of amending Section 12 of the National Insurance Act, 1911, in the direction suggested.

Medical Cards.

Mr. CHARLES BATHURST asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners, whether he was aware that the Insurance Commissioners had required in Memorandum 187 I.C., that no insured person would on and from Jan. 12th last be able, without a medical card, to exercise a choice of, or to claim treatment from, a doctor selected by him; that in spite of such regulations the medical cards had not reached insured persons in several hundred thousands of cases, with the result that they were wholly unable to obtain medical benefit when sick except at their own expense; and whether, as in such cases insured persons were being deprived of the benefit promised to them as the result of their own and their employers' contributions, the Government proposed to take any and, if any, what action in the matter.—Mr. WEDGWOOD BENN answered: Under the arrangements indicated in the memorandum in question doctors are not permitted to require the persons on their lists to produce medical cards as a condition of their receiving treatment until notified by the Insurance Committee that medical cards have been issued to all such persons. Those arrangements, moreover, provide a special procedure whereby persons who desire to choose a doctor may obtain a medical card for the purpose upon application, and my right honourable friend has no reason to believe that there is any ground for the apprehension of the honourable Member.

Surcharging for Drugs.

Mr. GODFREY LOCKER-LAMPSON asked the honourable Member for St. George's-in-the-East whether in the case of a deficiency in the drug fund in any district chemists who had not had their accounts paid for 1913 could surcharge the doctors for the amount if it was proved that the prescriptions had not been unreasonable.—Mr. WEDGWOOD BENN answered: The provisions of the Regulations as to surcharging apply only to prescriptions which are in excess of what is reasonable either in character or amount.

TUESDAY, MARCH 24TH.

Strike in Medical College, Lahore.

Mr. MACPHERSON asked the Under Secretary of State for India whether there was a strike of students in the Medical College, Lahore; if so, what was the cause of the strike; and whether he could say if there was an immediate prospect of its termination.—Mr. CHARLES ROBERTS replied: I have seen certain conflicting reports in the press as to the causes of the strike, but I am not in a position to make any statement. It is stated in the press that the strike is now ended.

The Drug Fund.

Mr. GODFREY LOCKER-LAMPSON asked the Prime Minister whether the Government would give facilities for the introduction of a Bill to provide a grant for those panel chemists whose accounts for 1913 could not be met out of the drug fund under the National Insurance Act.—Mr. ASQUITH answered: No, sir, I am not aware that a case has been made out for altering the arrangement under which the existing Parliamentary grant is given.

Medical Aspects of the Insurance Act.

Sir HENRY CRAIK called attention to the administration of medical relief under the National Insurance Act, and moved "That, in the opinion of this House, medical relief under the National Insurance Act is open to objection as regards some of its principles, inadequate in many respects, and likely to lead to serious difficulty, and that the supply of sanatorium benefit is greatly defective." The honourable Member said that 16,300 medical men were on the panels. There were many of them amongst the best of their profession ready to do honest work for their profession. But these panel practitioners were spread over 13,000,000 people, and a good many of them were duplicated on different panels. Patients were not equally distributed. There were cases where one doctor had over 3000 people on his list. The Act provided that these people were to receive adequate medical service. Was there time for skilled diagnosis in the case of men who had 2000 persons on their lists? What about provisions for operations? Nursing was not properly provided. The difficulties of hospitals had been increased and their resources crippled. Had adequate compensation been given for this? The honourable gentleman referred to malingering under the Act, and said that medical resented any suggestion that they were in any d responsible for conniving at it. The medical man's duty was to his patient, and he had to put that befor consideration of the funds of a Friendly Society. Government had involved themselves in a mass of com tions by adopting the system which they did in the Na Insurance Act.

Mr. GODFREY LOCKER-LAMPSON seconded. He said th would not deal with the part of the subject which honourable friend had spoken of. He would refer to matters on which the expectations of the public had deceived at the present time. In many thousands of sufferers from tuberculosis were not getting the treat which they were paying for. If the Act was to be fair, must be equality of treatment for everybody. The honour Member also raised the question of the deficiencies drug fund in certain areas of Lancashire and elsewhere. cause of trouble was not the unreasonable prescribing by doctors, but excessive sickness in industrial areas. drug fund was in danger of becoming bankrupt.

Mr. HERBERT SAMUEL said that it had to be rememb that "sanatorium benefit" as used in the Insurance Act not imply that every consumptive person must neces be sent during the whole period of his illness to a sanator The cases in their earliest stages were sometimes of doubtful diagnosis, and it was necessary for them to be wa at the dispensary or hospital. After a patient had been sanatorium, if the disease was arrested, he resumed ordinary daily life, and received domiciliary treatment the case grew worse the patient should have ho treatment. The Astor Committee reported that beds required in the sanatoria for insured persons 2100 and an equal number in hospitals. The num of beds provided in sanatoria in England for the persons who might need them and for others was and the number in hospitals 2580. Up to the presen fewer than 20,000 insured persons had received treatmen tuberculosis either at sanatoria or in hospitals. W certain additional beds which were contemplated were vided there would be 12,000 beds in the country for per suffering from this disease. For the first time an endea was being made to make provision for the whole of population. At the present moment the measures wer the most part only in the preparatory stage. There adequate accommodation in sanatoria for all insured per suffering from tuberculosis. There was not yet adeq accommodation for the whole population, but it was b provided. Eighty per cent. of the population of Eng were already covered by the schemes so far submitted b local authorities.

Mr. H. FORSTER pointed out that the Insurance C missioners had as yet been unable to arrange for the serv of consultants who would be required to deal with c requiring more specialised attention than a general pra tioner could be reasonably expected to give. He also as whether suitable treatment was always afforded in the ca of tuberculosis treated under the Insurance Act.

Mr. WEDGWOOD BENN (who represents the Insura Commissioners) asked the honourable Member (Sir Craik) whether the members of the medical profes authorised him to commit them to a voluntary syste insurance. If so, what were they to charge the patie Would they go on treating them at the same rate if the lives went outside the system of insurance?

Mr. LOCKER-LAMPSON: Will the honourable gentle say whether the chemists are to be paid or not?

Mr. WEDGWOOD BENN: Is the honourable gentle authorised by any body of chemists in Manchester or Sal to complain that any money owing to them is not paid?

Mr. LOCKER-LAMPSON: Will the honourable gentle give a pledge that the chemists will be paid?

Mr. WEDGWOOD BENN: When I have reason to sup that the chemists through authorised channels are ma that demand, an answer will be given to that question.

The motion was under discussion at 11 o'clock, whe the rules of the House further debate stood adjourned.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institut and others possessing information suitable for this column, invited to forward to THE LANCET *Office, directed to the Editor, not later than 9 o'clock on the Thursday morning of week, such information for gratuitous publication.*

BRERETON-BARRY, J., L.A.H., has been appointed Assistant Surgeo the Stockport Infirmary.

BROWN, J. PERCIVAL, M.B., Ch.B. Vict., has been appointed Me Officer of Health of Bacup.

EDINGTON, G. H., M.D., C.M. Glasg., has been appointed Lecture Clinical Surgery at the Glasgow University.

FIGDOR, PHILIP, M.B., Ch.B. Glasg., has been appointed Assis Medical Officer and Clinical Pathologist to the City of Westmi Union Infirmary, Hendon, N.W.

£2,421,071 over those of 1912. The total surplus of the two branches is £3,908,605, which is disposed of as follows: £1,250,000 to the Investments Reserve Funds, £2,198,854 to be distributed among participating policy-holders and the staff, and £459,751 to be carried forward. The directors' report is accompanied by the actuarial report of Mr. J. Burn. There are six Prudential Approved Societies under the National Insurance Act, 1911. Payment of sickness and maternity benefits commenced on Jan. 13th, 1913, and during the year a sum of £1,401,360 was distributed to members by the company's agents. The amount paid by the Approved Societies for expenses to the Industrial Branch of the Prudential was £296,630 6*s.* 3*d.*

EXPOSING CHILDREN IN ORDER TO OBTAIN ALMS.

AT the Marylebone police court recently Mr. Paul Taylor sentenced to 21 days' imprisonment a man who had been playing an organ in the streets at night while his wife sat on the shafts with an infant 12 months old in her arms. They had between them when arrested 11*s.* 3*d.* in silver and bronze, and an inspector of the National Society for the Prevention of Cruelty to Children stated that the man had once told him that he could earn 5*s.* a day by using his children in the manner described. Mr. Paul Taylor, in sentencing the male defendant and dismissing the case against the wife, said that to permit such a practice would be to put a premium upon cruelty. The man, we have seen stated, was in a deplorable condition of health.

A CATALOGUE OF MEDICAL BOOKS.

CATALOGUES of medical or other special books, when well prepared with a good index, are not only needed by those who intend to purchase some of the works enumerated, but are also useful as reference books in themselves to past and current literature and as a ready means of knowing what has been written on any one special subject or of refreshing the memory as to the exact title of a work which may be well known but whose specific designation cannot be recalled at the moment by a dormant memory. It might even be desirable to have a catalogue of catalogues. Messrs. Butterworth's "Medical Catalogue for 1914," with 202 pages, is a most useful catalogue and has been well prepared, and firms which prepare books of this sort should be encouraged. It may be obtained by medical men on addressing Messrs. Butterworth and Co. (Australia), Limited, 4, Bell-yard, Temple Bar, London, or 76, Elizabeth-street, Sydney, New South Wales.

J. N.—Particulars of the Salisbury treatment were given in THE LANCET of July 3rd (p. 11) and 10th (p. 115), 1897.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 13th and 14th (Berlin).—Thirteenth Congress of the German Orthopædic Society.
„ 13th–16th (New York).—Fourth Congress of the International Surgical Society. (President: Prof. Depage. Bruxelles.)
„ 15th–18th (Berlin).—Forty-third Congress of the German Surgical Society.
„ 19th–21st (Berlin).—"Jubilee" Congress of the German Röntgen Society.
„ 20th–23rd (Wiesbaden).—Thirty-first German Congress for Internal Medicine.
„ 27th–May 1st (London, Royal Horticultural Hall).—Nursing Conference and Exhibition.
May 1st–Nov. 1st (Lyons).—International Town Hygiene Exhibition.
May (London, Imperial Institute).—Victoria League Imperial Health Conference.
May–October (London, Shepherd's Bush).—Anglo-American Exposition.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

---

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions, post free from THE LANCET Offices have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to India whose rates of pay, including) per month)

commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London W C

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied
